

u-blox 8 / u-blox M8

Receiver description

Including protocol specification

Abstract

The receiver description including protocol specification describes the firmware features, specifications and configuration for u-blox 8 / u-blox M8 high performance positioning modules.

The receiver description provides an overview and conceptual details of the supported features. The protocol specification describes the NMEA and RTCM protocols as well as the UBX protocol (version 15. 00 up to 19.20, version 20.00 to 20.30, version 22.00 to 22.01 and version 23.00 to 23.01) and serves as a reference manual. It includes the standard precision GNSS, Time Sync, Time & Frequency Sync, High precision GNSS, ADR and UDR products.

Preface

1 Document Overview

The interface description including receiver description is an important resource for integrating and configuring u-blox receivers. This document has a modular structure and it is not necessary to read it from the beginning to the end. There are two main sections: The Receiver Description and the Interface Description.

The Receiver Description describes the software aspects of system features and configuration of u-blox receivers. The Receiver Description is structured according to areas of functionality, with links provided to the corresponding NMEA and UBX messages, which are described in the Interface Description.

The Interface Description is a reference describing the messages used by the u-blox receiver and is organized by the specific NMEA, UBX, and RTCM messages.

This document provides general information on u-blox receivers. Some information might not apply to certain products. Refer to the product data sheet and/or integration manual for possible restrictions or limitations.

2 Firmware and Protocol Versions

The protocol version defines a set of messages that are applicable across various u-blox products. Each firmware used by a u-blox receiver supports a specific protocol version, which is not configurable.

The following sections will explain how to decode the shown information to get the firmware and the protocol version.

2.1 How to Determine the Version and the Location of the Firmware

The u-blox receiver contains a firmware in two different locations:

- Internal ROM
- · External flash memory

The location and the version of the currently running firmware can be found in the boot screen or in the UBX-MON-VER message.

For firmware supporting Protocol Version 17 and below:

- · Boot screen, Protocol Version 17 and below
- UBX-MON-VER, Protocol Version 17 and below

For firmware supporting Protocol Version from 18 to 23.01:

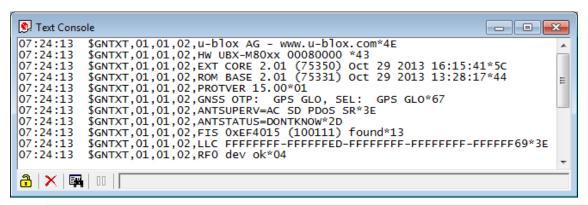

- Boot screen, Protocol Version from 18 to 23.01
- UBX-MON-VER, Protocol Version 18 to 23.01

2.1.1 Decoding the Boot Screen (for Protocol Version 17 and Below)

Boot screen for a u-blox receiver running from ROM:

Boot screen for a u-blox receiver running from flash:

Not every line is output by every u-blox receiver in the boot screen. This depends on the product, the firmware location and the firmware version.

Possible lines in the boot screen and their meanings:

| 3 . | |
|-----------------------------|---|
| Entry | Description |
| u-blox AG - www.u-blox.com | Start of the boot screen |
| HW UBX-M80xx 00800000 | Hardware version of the u-blox receiver (u-blox M8 receiver) |
| ROM CORE 2.01 (75331) | Firmware version 2.01 running from ROM (revision number) |
| Oct 29 2013 13:28:17 | compilation date/time |
| EXT CORE 2.01 (75350) | Firmware version 2.01 running from flash (revision number) |
| Oct 29 2013 16:15:41 | compilation date/time |
| ROM BASE 2.01 (75331) | Underlying firmware version 2.01 in ROM (revision number) |
| Oct 29 2013 13:28:17 | compilation date/time |
| PROTVER 15.00 | Supported protocol version |
| GNSS OTP: GPS GLO, | Default Major GNSS selection. |
| SEL: GPS GLO | Current Major GNSS selection. |
| ANTSUPERV=AC SD PDoS SR | Configuration of the Antenna supervisor where |
| | AC: Active Antenna Control enabled |
| | SD: Short Circuit Detection enabled |
| | OD: Open Circuit Detection enabled |
| | PDoS: Short Circuit Power Down Logic enabled |
| | SR: Automatic Recovery from Short state |
| LLC FFFFFFFF-FF7F7C3F- | Low-level configuration of the u-blox receiver. |
| FFFFFF96-FFFFFFF-FFFFF79 | |
| FIS 0xEF4015 (100111) found | Flash Information Structure (FIS) file for flash memory with |
| | JEDEC 0xEF4015 found in the external flash memory. Revision |
| | number of the file is indicated in brackets. |

Possible lines in the boot screen and their meanings: continued

| Entry | Description |
|------------|------------------------------------|
| RFO dev ok | RF channel 0 configured correctly. |

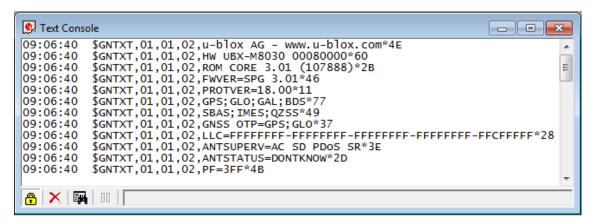

The line containing the CORE indicates which version of the firmware is currently running. The firmware is running either from ROM (indicated with ROM CORE) or from external flash memory (indicated with EXT CORE).

The line containing the CORE is called **firmware string** in the rest of the document.

2.1.2 Decoding the Boot Screen (for Protocol Version from 18 to 23.01)

Boot screen for a u-blox receiver running from ROM:

Boot screen for a u-blox receiver running from flash:

Not every line is output by every u-blox receiver in the boot screen. This depends on the product, the firmware location and the firmware version.

Possible lines in the boot screen and their meanings:

| Entry | Description |
|----------------------------|---|
| u-blox AG - www.u-blox.com | Start of the boot screen |
| HW UBX-M8030 00800000 | Hardware version of the u-blox receiver (u-blox M8 receiver) |
| HW UBX-G8020 00800000 | Hardware version of the u-blox receiver (u-blox 8 receiver) |
| ROM CORE 3.01 (107888) | Firmware version 3.01 running from ROM (revision number) |
| EXT CORE 3.01 (107900) | Firmware version 3.01 running from flash (revision number) |
| ROM BASE 3.01 (107888) | Underlying firmware version 3.01 in ROM (revision number) |

Possible lines in the boot screen and their meanings: continued

| Entry | Description |
|--------------------------|--|
| FWVER=SPG 3.01 | Firmware of product category and version where |
| | SPG: Firmware of Standard Precision GNSS product |
| | HPG: Firmware of High Precision GNSS product |
| | ADR: Firmware of ADR product |
| | UDR: Firmware of UDR product |
| | TIM: Firmware of Time Sync product |
| | FTS: Firmware of Time & Frequency Sync product |
| PROTVER=18.00 | Supported protocol version |
| MOD=NEO-M8N-0 | Module identification. Set in production. |
| FIS=0xEF4015 (100111) | Flash Information Structure (FIS) file for flash memory with |
| | JEDEC 0xEF4015 found in the external flash memory. Revision |
| | number of the file is indicated in brackets. |
| GPS;GLO;GAL;BDS | Supported Major GNSS. |
| SBAS; IMES; QZSS | Supported Augmentation systems. |
| GNSS OTP=GPS;GLO | Default Major GNSS selection. |
| LLC FFFFFFFF-FFFFFF- | Low-level configuration of the u-blox receiver. |
| FFFFFFF-FFFFFFF-FFCFFFFF | |
| ANTSUPERV=AC SD PDoS SR | Configuration of the Antenna supervisor where |
| | AC: Active Antenna Control enabled |
| | SD: Short Circuit Detection enabled |
| | OD: Open Circuit Detection enabled |
| | PDoS: Short Circuit Power Down Logic enabled |
| | SR: Automatic Recovery from Short state |
| PF=3FF | Product configuration. |

The line containing the FWVER indicates which version of the firmware is currently running and is called **firmware version** in the rest of the document.

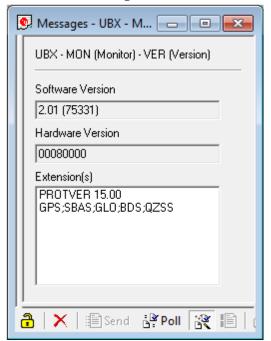

The numbers in parentheses (revision numbers) should only be used to identify a known firmware version and are not guaranteed to increase over time.

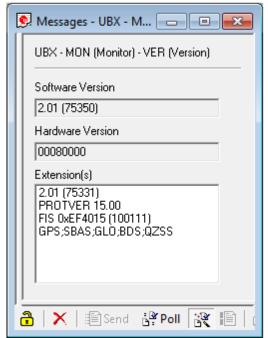

2.1.3 Decoding the output of UBX-MON-VER (for Protocol Version 17 and below)

UBX-MON-VER for receiver running from ROM

UBX-MON-VER for receiver running from Flash

Possible fields in UBX-MON-VER and their meanings:

| Entry | Description |
|------------------|--|
| Software Version | Currently running firmware version. |
| | If no firmware version is shown in the first line of Extension(s), |
| | then the u-blox receiver runs from ROM . |
| | If a firmware version is shown in the first line of Extension(s), |
| | then the u-blox receiver runs from flash . |
| Hardware Version | The hardware version of the u-blox receiver. |
| Extension(s) | Extended information about the u-blox receiver firmware. See |
| | table below for the entries. |

Not every entry is output by every u-blox receiver in the UBX-MON-VER extensions. This depends on the product, the firmware location and the firmware version.

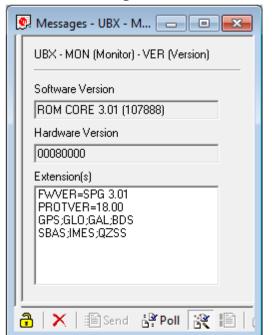

Possible entries in UBX-MON-VER Extension(s):

| | • , |
|-----------------------|---|
| Entry | Description |
| 2.01 (75331) | Underlying firmware version in ROM. |
| | If such an entry is present, then the u-blox receiver runs from |
| | flash. |
| PROTVER 15.00 | Supported protocol version. |
| FIS 0xEF4015 (100111) | Flash Information Structure (FIS) file for flash memory with |
| | JEDEC 0xEF4015 found in the external flash memory. Revision |
| | number of the file is indicated in brackets. |
| MOD NEO-M8N-0 | Module identification. Set in production. |
| GPS;SBAS;GLO;BDS;QZSS | Supported GNSS. |

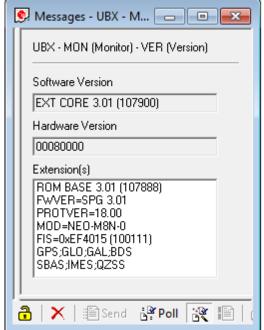

2.1.4 Decoding the output of UBX-MON-VER (for Protocol Version from 18 and 23.01)

UBX-MON-VER for receiver running from ROM

UBX-MON-VER for receiver running from Flash

Possible fields in UBX-MON-VER and their meanings:

| Entry | Description |
|------------------------|--|
| Software Version | Currently running firmware version. |
| ROM CORE 3.01 (107888) | If ROM CORE, then the u-blox receiver runs from ROM . |
| EXT CORE 3.01 (107900) | If EXT CORE, then the u-blox receiver runs from Flash . |
| Hardware Version | The hardware version of the u-blox receiver. |
| Extension(s) | Extended information about the u-blox receiver firmware. See |
| | table below for the entries. |

Not every entry is output by every u-blox receiver in the UBX-MON-VER extensions. This depends on the product, the firmware location and the firmware version.

Possible entries in UBX-MON-VER Extension(s):

| Entry | Description |
|------------------------|---|
| ROM BASE 3.01 (107888) | Underlying firmware version in ROM. |
| | If such an entry is present, then the u-blox receiver runs from |
| | flash. |
| FWVER=SPG 3.01 | Firmware of product category and version where |
| | SPG: Firmware of Standard Precision GNSS product |
| | HPG: Firmware of High Precision GNSS product |
| | ADR: Firmware of ADR product |
| | UDR: Firmware of UDR product |
| | TIM: Firmware of Time Sync product |
| | FTS: Firmware of Time & Frequency Sync product |
| PROTVER=18.00 | Supported protocol version. |
| MOD=NEO-M8N-0 | Module identification. Set in production. |

Possible entries in UBX-MON-VER Extension(s): continued

| Entry | Description |
|-----------------------|--|
| FIS=0xEF4015 (100111) | Flash Information Structure (FIS) file for flash memory with |
| | JEDEC 0xEF4015 found in the external flash memory. Revision |
| | number of the file is indicated in brackets. |
| GPS;GLO;GAL;BDS | Supported Major GNSS. |
| SBAS; IMES; QZSS | Supported Augmentation systems. |

2.2 How to Determine the Supported Protocol Version of the u-blox Receiver

Each u-blox receiver reports its supported protocol version in the following ways:

- On start-up in the boot screen
- In the UBX-MON-VER message

with the line containing PROTVER (example: PROTVER=18.00).

Additionally, the firmware string, together with the firmware version, can be used to look up the corresponding protocol version. The tables below give an overview of the released firmware and their corresponding protocol versions.

2.2.1 u-blox 8 / u-blox M8 Firmware and Supported Protocol Versions

Firmware for Standard Precision GNSS products

| Firmware version | Firmware string | Protocol Version |
|------------------|--|------------------|
| SPG 2.01 | ROM CORE 2.01 (75331) Oct 29 2013 13:28:17 | 15.00 |
| SPG 2.01 | EXT CORE 2.01 (75350) Oct 29 2013 16:15:41 | 15.00 |
| SPG 3.01 | ROM CORE 3.01 (107888) | 18.00 |
| SPG 3.01 | EXT CORE 3.01 (107900) | 18.00 |
| SPG 3.05 | EXT CORE 3.05 (a5d3549) | 18.00 |
| SPG 3.50 | EXT CORE 3.50 (190461) | 23.00 |
| SPG 3.51 | ROM CORE 3.51 (19dc23) | 23.01 |
| SPG 3.51 | EXT CORE 3.51 (19dc23) | 23.01 |

Firmware for High Precision GNSS Products

| Firmware version | Firmware string | Protocol Version |
|------------------|------------------------|------------------|
| HPG 1.00 | EXT CORE 3.01 (111160) | 20.00 |
| HPG 1.11 | EXT CORE 3.01 (b8bc67) | 20.01 |
| HPG 1.20 | EXT CORE 3.01 (d34ed4) | 20.10 |
| HPG 1.30 | EXT CORE 3.01 (d080e3) | 20.20 |
| HPG 1.40 | EXT CORE 3.01 (db0c89) | 20.30 |
| HPG 1.43 | EXT CORE 3.05 (ff96ba) | 20.30 |

Firmware for Dead Reckoning products

| Firmware version | Firmware string | Protocol Version |
|------------------|---|------------------|
| ADR 3.00 | EXT CORE 2.01 (77076) Dec 18 2013 09:40:24 ADR 3.00 | 15.00 |

Receiver Description

3 Receiver Configuration

3.1 Configuration Concept

u-blox receivers are fully configurable with UBX protocol configuration messages (message class UBX-CFG). The configuration used by the u-blox receiver during normal operation is called "Current Configuration". The Current Configuration can be changed during normal operation by sending any UBX-CFG-XXX message to the u-blox receiver over an I/O port. The u-blox receiver will change its Current Configuration immediately after receiving the configuration message. The u-blox receiver always uses only the Current Configuration.

Unless the Current Configuration is made permanent by using UBX-CFG-CFG as described below, the Current Configuration will be lost when there is:

- · a power cycle
- a hardware reset
- a (complete) controlled software reset

See the section on resetting a u-blox receiver for details.

The Current Configuration can be made permanent (stored in a non-volatile memory) by saving it to the "Permanent Configuration". This is done by sending a UBX-CFG-CFG message with an appropriate **saveMask** (UBX-CFG-CFG/save).

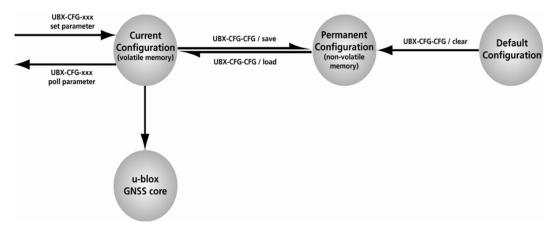

The Permanent Configuration is copied to the Current Configuration during start-up or when a UBX-CFG-CFG message with an appropriate **loadMask** (UBX-CFG-CFG/load) is sent to the u-blox receiver.

The Permanent Configuration can be restored to the u-blox receiver's Default Configuration by sending a UBX-CFG-CFG message with an appropriate **clearMask** (UBX-CFG-CFG/clear) to the u-blox receiver. This only replaces the Permanent Configuration, not the Current Configuration. To make the u-blox receiver operate with the Default Configuration which was restored to the Permanent Configuration, a UBX-CFG-CFG/load command must be sent or the u-blox receiver must be reset.

The mentioned masks (saveMask, loadMask, clearMask) are 4-byte bitfields. Every bit represents one configuration sub-section. These sub-sections are defined in section "Organization of the Configuration Sections". All three masks are part of every UBX-CFG-CFG message. Save, load and clear commands can be combined in the same message. Order of execution is: clear, save, load.

The following diagram illustrates the process:

It is possible to change the current communications port settings using a UBX-CFG-CFG message. This could affect baud rate and other transmission parameters. Because there may be messages queued for transmission there may be uncertainty about which protocol applies to such messages. In addition a message currently in transmission may be corrupted by a protocol change. Host data reception parameters may have to be changed to be able to receive future messages, including the acknowledge message associated with the UBX-CFG-CFG message.

3.2 Organization of the Configuration Sections

The configuration is divided into several sub-sections. Each of these sub-sections corresponds to one or several UBX-CFG-XXX messages. The sub-section numbers in the following tables correspond to the bit position in the masks mentioned above. All values not listed are reserved.

Configuration sub-sections

| Number | Name | CFG messages | Description |
|--------|------|----------------|--|
| 0 | PRT | UBX-CFG-PRT | Port and USB settings |
| | | UBX-CFG-USB | |
| 1 | MSG | UBX-CFG-MSG | Message settings (enable/disable, update rate) |
| 2 | INF | UBX-CFG-INF | Information output settings (Errors, Warnings, Notice, |
| | | | Test etc.) |
| 3 | NAV | UBX-CFG-NAV5 | Settings for Navigation Parameters, Receiver Datum, |
| | | UBX-CFG-NAVX5 | Measurement and Navigation Rate, SBAS, NMEA |
| | | UBX-CFG-DAT | protocol and Time mode (Timing products only) |
| | | UBX-CFG-RATE | |
| | | UBX-CFG-SBAS | |
| | | UBX-CFG-NMEA | |
| | | UBX-CFG-TMODE2 | |
| 4 | RXM | UBX-CFG-GNSS | GNSS Settings, Power Mode Settings, Time Pulse |
| | | UBX-CFG-TP5 | Settings, Jamming/Interference Monitor Settings |

| | | LOGFILTER | |

Configuration sub-sections continued

| Number | Name | CFG messages | Description |
|--------|------|--------------|---|
| 12 | FTS | UBX-CFG-DOSC | Disciplining configuration. Only applicable to the Time & |
| | | UBX-CFG-ESRC | Frequency Sync product. |
| | | UBX-CFG-SMGR | |

3.3 Permanent Configuration Storage Media

The Current Configuration is stored in the volatile RAM of the u-blox receiver. Hence, any changes made to the Current Configuration without saving will be lost if any of the reset events listed in the section above occur. By using UBX-CFG-CFG/save, the selected configuration sub-sections are saved to all non-volatile memories available:

- On-chip BBR (battery backed RAM). In order for the BBR to work, a backup battery must be applied to the u-blox receiver.
- External flash memory, where available.

3.4 u-blox Receiver Default Configuration

The Permanent Configuration can be reset to Default Configuration through a UBX-CFG-CFG/clear message. The Default Configuration of the u-blox receiver is normally determined when the u-blox receiver is manufactured. Refer to specific product data sheet for further details.

3.5 Save-on-Shutdown Feature

The save-on-shutdown feature (SOS) enables the u-blox receiver to store the contents of the battery-backed RAM to an external flash memory and restore it upon startup. This allows the u-blox receiver to preserve some of the features available only with a battery backup (preserving configuration and satellite orbit knowledge) without having a battery backup supply present. It does not, however, preserve any kind of time knowledge. The save-on-shutdown must be commanded by the host. The restore-on-startup is automatically done if the corresponding data is present in the flash. No expiration check of the data is done.

The following outlines the suggested shutdown procedure when using the save-on-shutdown feature:

- With the UBX-CFG-RST message, the host commands the u-blox receiver to stop, specifying reset mode 0x08 ("Controlled GNSS stop") and a BBR mask of 0 ("Hotstart").
- The u-blox receiver confirms the reception of a valid / invalid request with a UBX-ACK-ACK / UBX-ACK-NAK message.
- The host commands the saving of the contents of BBR to the flash memory using the UBX-UPD-SOS-BACKUP message.
- The u-blox receiver confirms the reception of a valid / invalid request with a UBX-ACK-ACK / UBX-ACK-NAK message.
- For a valid request the u-blox receiver reports on the success of the backup operation with a UBX-UPD-SOS-ACK message.
- The host powers off the u-blox receiver.

Do not expect UBX-CFG-RST and UBX-UPD-SOS-BACKUP message to be acknowledged with a UBX-ACK-ACK / UBX-ACK-NAK message by the receiver with newer FW versions.

And consequently the startup procedure is as follows:

- The host powers on the u-blox receiver.
- The u-blox receiver detects the previously stored data in flash. It restores the corresponding memory and reports the success of the operation with a UBX-UPD-SOS-RESTORED message on the port where it had received the save command message (if the output protocol filter on that port allows it). It does not report anything if no stored data has been detected.
- Additionally the u-blox receiver outputs a UBX-INF-NOTICE and/or a NMEA-TXT message with the contents RESTORED in the boot screen (depends on port and information messages configuration) upon success.
- Optionally the host can deliver coarse time assistance using UBX-MGA-INI-TIME_UTC for better startup performance.

Once the u-blox receiver has started up it is suggested to delete the stored data using a <code>UBX-UPD-SOS-CLEAR</code> message. The u-blox receiver responds with a <code>UBX-ACK-ACK</code> or <code>UBX-ACK-NAK</code> message.

Note that this feature must not be used with power save mode and that saved data must be deleted before switching to that mode.

4 Concurrent GNSS

Many u-blox positioning modules and chips are multi-GNSS receivers capable of receiving and processing signals from multiple Global Navigation Satellite Systems (GNSS).

u-blox concurrent GNSS receivers are multi-GNSS receivers that can acquire and track satellites from more than one GNSS system at the same time, and utilize them in positioning.

4.1 GNSS Types

u-blox receivers support a wide range of different GNSS. Some GNSS have large numbers of satellites deployed globally and therefore are generally capable of providing navigation solutions on their own. u-blox designates these as "major GNSS". By contrast, some are designed to be used to enhance the use of one or more major GNSS and u-blox designates these "augmentation systems".

In many cases, such as Satellite Numbering, this distinction does not matter as u-blox receivers generally try to combine information from all available GNSS to create the best possible navigation information. However, particularly in relation to configuring the receiver, the distinction can be important.

4.1.1 Major GNSS

The major GNSS supported by u-blox receivers are described below.

4.1.1.1 GPS

The Global Positioning System (GPS) is a GNSS operated by the US department of defense. Its purpose is to provide position, velocity and time for civilian and defense users on a global basis. The system currently consists of 32 medium earth orbit satellites and several ground control stations.

4.1.1.2 GLONASS

GLONASS is a GNSS operated by Russian Federation department of defense. Its purpose is to provide position, velocity and time for civilian and defense users on a global basis. The system consists of 24 medium earth orbit satellites and ground control stations.

It has a number of significant differences when compared to GPS. In most cases, u-blox receivers operate in a very similar manner when they are configured to use GLONASS signals instead of GPS. However some aspects of receiver output are likely to be noticeably affected.

4.1.1.3 Galileo

At the time of writing (early 2018), the Galileo system was still under development with only a few fully operational SVs. Therefore, the precise performance and reliability of ublox receivers when receiving Galileo signals is effectively impossible to guarantee.

Galileo is a GNSS operated by the European Union. Its purpose is to provide position, velocity and time for civilian users on a global basis. The system is currently not fully operational. It is eventually expected to consist of 30 medium earth orbit satellites.

On u-blox M8 receivers a maximum of ten channels can be assigned to Galileo for signal acquisition and tracking. Note that at most eight Galileo satellites will be used for navigation. It is recommended not to set the number of Galileo channels higher than eight in UBX-CFG-GNSS.

4.1.1.3.1 Search and Rescue Return Link Message

The receiver supports reception and output of Search and Rescue (SAR) Return Link Messages (RLM). When enabled, a UBX-RXM-RLM message will be generated whenever an RLM is detected by the receiver.

At the time of writing (early 2018), no live transmission of RLMs by Galileo SVs had been observed, so the details of their use was impossible to verify completely.

4.1.1.4 BeiDou

BeiDou is a GNSS operated by China. Its purpose is to initially provide position, velocity and time for users in Asia. In a later stage when the system is fully deployed it will have worldwide coverage. The full system will consist of five geostationary, five inclined geosynchronous and 27 medium earth orbit satellites, as well as control, upload and monitoring stations. Although this implies a full constellation of 37 SVs, only SVs numbered 1 to 30 are fully supported in the D1/D2 NAV message described by the Interface Control Document version 2.0. For SVs numbered above 30, there is currently no almanac or differential correction. Consequently, u-blox receivers only use BeiDou SVs numbered 1 to 30.

4.1.2 Augmentation Systems

The augmentation systems supported by u-blox receivers are described below.

4.1.2.1 SBAS

There are a number of Space Based Augmentation Systems (SBAS) operated by different countries using geostationary satellites. u-blox receivers currently support the following:

- WAAS (Wide Area Augmentation System) operated by the US.
- EGNOS (European Geostationary Navigation Overlay Service) operated by the EU.
- MSAS (Multi-functional Satellite Augmentation System) operated by Japan.
- GAGAN (GPS Aided Geo Augmented Navigation) operated by India.

See section SBAS for more details.

4.1.2.2 QZSS

The Quasi Zenith Satellite System (QZSS) is a regional satellite augmentation system operated by Japan Aerospace Exploration Agency (JAXA). It is intended as an enhancement to GPS, to increase availability and positional accuracy. The QZSS system achieves this by transmitting GPS-compatible signals in the GPS bands.

NMEA messages will show the QZSS satellites only if configured to do so (see section Satellite Numbering).

The QZSS L1SAIF is an additional signal broadcast by QZSS satellites that contains augmentation and other data.

4.1.2.3 IMES

The Indoor MEssaging System (IMES) is an extension to the QZSS specification. See section IMES for more details.

4.2 Configuration

The UBX-CFG-GNSS message allows the user to specify which GNSS signals should be processed along with limits on how many tracking channels should be allocated to each GNSS. The receiver will respond to such a request with a UBX-ACK-ACK message if it can support the requested configuration or a UBX-ACK-NAK message if not.

Customers enabling BeiDou and/or Galileo who wish to use the NMEA protocol are recommended to select NMEA version 4.1, as earlier versions have no support for these two GNSS. See the NMEA protocol section for details on selecting NMEA versions.

The combinations of systems which can be configured simultaneously depends on the receiver's capability to receive several carrier frequencies. The UBX-MON-GNSS message reports which major GNSS can be selected. Refer to the data sheet of the corresponding u-blox receiver for full information. Usually GPS, SBAS (e.g. WAAS, EGNOS, MSAS), QZSS and Galileo can be enabled together, because they all use the 1575.42MHz L1 frequency. GLONASS and BeiDou both operate on different frequencies, therefore the receiver must be able to receive a second or even third carrier frequency in order to process these systems together with GPS.

It is recommended to disable GLONASS and BeiDou if a GPS-only antenna or GPS-only SAW filter is used.

In all circumstances, it is necessary for at least one major GNSS to be enabled. It is also required that at least 4 tracking channels are available to each enabled major GNSS, i.e. maxTrkCh must have a minimum value of 4 for each enabled major GNSS. Further requirements on generating configurations acceptable by the receiver can be found in UBX-CFG-GNSS.

4.2.1 Switching between GNSS

Users should be aware that switching between GNSS (and especially away from GPS) may affect the long term accuracy of the receiver until the next cold start. In normal operation the receiver selects the best models and corrections from the transmitted auxiliary data (e.g. UTC and lonospheric parameters), basing this selection on the configured GNSS. Disabling a major GNSS prevents auxiliary data from that GNSS being refreshed and so it will become stale, resulting in progressively degraded performance. This can occur even if the main power supply is removed, as most receivers retain auxiliary data in non-volatile storage, e.g. battery backed RAM (BBR). For this reason, u-blox recommends that receivers are cold started after any change that disables an

active GNSS, within a few weeks, but preferably immediately. This will ensure that the receiver then uses only regularly refreshed information from the newly configured constellations.

4.2.2 Configuring QZSS L1SAIF

By default the receiver will be configured for QZSS L1C/A, this can be changed so the receiver can be configured for QZSS L1SAIF also. See the table below for UBX-CFG-GNSS sigCfgMask settings for signals on QZSS. For example, to enable QZSS L1C/A and QZSS L1SAIF, set the gnssId to 5 (for QZSS) and sigCfgMask to 0x05. If supported by the firmware, L1SAIF would then be enabled.

QZSS Signal configuration for UBX-CFG-GNSS

| Gnssld | Description | Signal mask |
|--------|-------------|--------------------|
| 5 | QZSS | 0x01 = QZSS L1C/A |
| | | 0x04 = QZSS L1SAIF |

5 SBAS Configuration Settings Description

5.1 SBAS (Satellite Based Augmentation Systems)

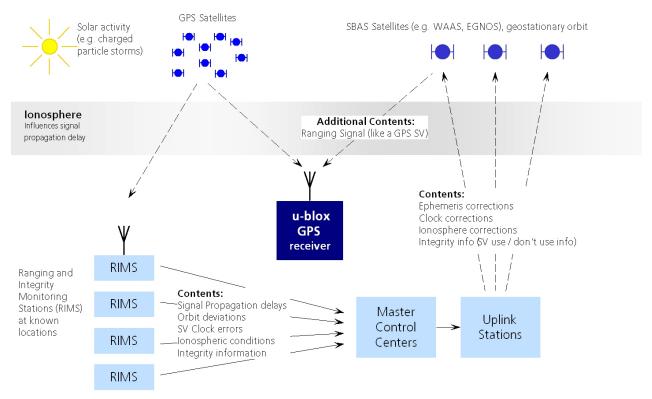

SBAS (Satellite Based Augmentation System) is an augmentation technology for GPS, which calculates GPS integrity and correction data with RIMS (Ranging and Integrity Monitoring Stations) on the ground and uses geostationary satellites to broadcast GPS integrity and correction data to GPS users. The correction data is transmitted on the GPS L1 frequency (1575.42 MHz), and therefore no additional receiver is required to make use of the correction and integrity data.

u-blox receivers will only process corrections for GPS. Other corrections are not applied, even if, as planned, some SBAS satellites start to transmit them (e.g. SDCM for GLONASS).

SBAS Principle

There are several compatible SBAS systems available or in development all around the world:

- WAAS (Wide Area Augmentation System) for North America has been in operation since 2003.
- MSAS (Multi-Functional Satellite Augmentation System) for Japan has been in operation since 2007.
- EGNOS (European Geostationary Navigation Overlay Service) has been in operation since 2009.
- GAGAN (GPS Aided Geo Augmented Navigation), for India has been in operation since 2014.
- SDCM (System for Differential Corrections and Monitoring), for Russia is at the time of writing in test mode.

Support of SBAS allows u-blox GPS technology to take full advantage of the augmentation systems that are currently available (i.e. WAAS, EGNOS, MSAS, GAGAN). Signals from systems currently being tested and/or planned (such as SDCM) may also work, when those systems become fully operational, but this cannot be relied upon and u-blox receivers are not configured to support them by default.

With SBAS enabled, the user benefits from additional satellites for ranging (navigation). u-blox GPS technology uses the available SBAS satellites for navigation just like GPS satellites, if the SBAS satellites offer this service.

To improve position accuracy, SBAS uses different types of correction data:

- Fast Corrections for short-term disturbances in GPS signals (due to clock problems, etc.).
- Long-term corrections for GPS clock problems, broadcast orbit errors etc.
- Ionosphere corrections for lonosphere activity

Another benefit of SBAS is the use of GPS integrity information. In this way SBAS control stations can 'disable' the use of GPS satellites within a 6-second alarm time in case of major GPS satellite problems. If integrity monitoring is enabled, u-blox GPS technology only uses satellites, for which

integrity information is available.

For more information on SBAS and associated services, refer to the following resources:

- RTCA/DO-229D (MOPS). Available from www.rtca.org
- gps.faa.gov for information on WAAS.
- www.esa.int for information on EGNOS.
- www.essp-sas.eu for information about European Satellite Services Provider (ESSP), the EGNOS operations manager.
- www.isro.org for information on GAGAN.
- www.sdcm.ru for information on SDCM.

SBAS satellites tracked (as of November 2015)

| Identification | Position | GPS PRN | SBAS Provider |
|--------------------|----------|---------|---------------|
| AMR | 98° W | 133 | WAAS |
| PanAmSat Galaxy XV | 133.0° W | 135 | WAAS |
| TeleSat Anik F1R | 107.3° W | 138 | WAAS |
| Inmarsat 3F2 AOR-E | 15.5° W | 120 | EGNOS |
| Artemis | 21.5° W | 124 | EGNOS |
| Inmarsat 3F5 IOR-W | 25° E | 126 | EGNOS |
| MTSAT-1R | 140.1° E | 129 | MSAS |
| MTSAT-2 | 145° E | 137 | MSAS |
| Inmarsat-4F1/IOR | 64° E | 127 | GAGAN |
| GSAT-10 | 83° E | 128 | GAGAN |

5.2 SBAS Features

This u-blox SBAS implementation is, in accordance with standard RTCA/DO-229D, a class Beta-1 equipment. All timeouts etc. are chosen for the En Route Case. Do not use this equipment under any circumstances for "safety of life" applications!

u-blox receivers are capable of receiving multiple SBAS signals concurrently, even from different SBAS systems (WAAS, EGNOS, MSAS, etc.). They can be tracked and used for navigation simultaneously. Every tracked SBAS satellite utilizes one vacant receiver tracking channel. Only the number of receiver channels limits the total number of satellites used. Every SBAS satellite that broadcasts ephemeris or almanac information can be used for navigation, just like a normal GPS satellite.

For receiving correction data, the u-blox receiver automatically chooses the best SBAS satellite as its primary source. It will select only one since the information received from other SBAS satellites is redundant and/or could be inconsistent. The selection strategy is determined by the proximity of the satellites, the services offered by the satellite, the configuration of the receiver (Testmode allowed/disallowed, Integrity enabled/disabled) and the signal link quality to the satellite.

If corrections are available from the chosen SBAS satellite and used in the navigation calculation, the DGPS flag is set in the receiver's output protocol messages (see UBX-NAV-PVT, UBX-NAV-SOL, UBX-NAV-STATUS, UBX-NAV-SVINFO, NMEA Position Fix Flags description). The message UBX-NAV-SBAS provides detailed information about which corrections are available and applied.

The most important SBAS feature for accuracy improvement is lonosphere correction. The measured data from regional RIMS stations are combined to make a TEC (Total Electron Content) Map. This map is transferred to the receiver via the satellites to allow a correction of the

ionosphere error on each received satellite.

Supported SBAS messages

| Message Type | Message Content | Source |
|--------------|--|---------|
| 0(0/2) | Test Mode | All |
| 1 | PRN Mask Assignment | Primary |
| 2, 3, 4, 5 | Fast Corrections | Primary |
| 6 | Integrity | Primary |
| 7 | Fast Correction Degradation | Primary |
| 9 | Satellite Navigation (Ephemeris) | All |
| 10 | Degradation | Primary |
| 12 | Time Offset | Primary |
| 17 | Satellite Almanac All | |
| 18 | Ionosphere Grid Point Assignment Primary | |
| 24 | Mixed Fast / Long term Corrections Primary | |
| 25 | Long term Corrections Primary | |
| 26 | Ionosphere Delays | Primary |

Each satellite services a specific region and its correction signal is only useful within that region. Planning is crucial to determine the best possible configuration, especially in areas where signals from different SBAS systems can be received:

Example 1: SBAS Receiver in North America

In the eastern parts of North America, make sure that EGNOS satellites do not take preference over WAAS satellites. The satellite signals from the EGNOS system should be disallowed by using the PRN Mask.

Example 2: SBAS Receiver in Europe

Some WAAS satellite signals can be received in the western parts of Europe, therefore it is recommended that the satellites from all but the EGNOS system should be disallowed using the PRN Mask.

Although u-blox receivers try to select the best available SBAS correction data, it is recommended to configure them to disallow using unwanted SBAS satellites.

The EGNOS SBAS system does not provide the satellite ranging function.

5.3 SBAS Configuration

To configure the SBAS functionalities use the UBX proprietary message UBX-CFG-SBAS (SBAS Configuration).

SBAS Configuration parameters

| Parameter | Description |
|------------------------------|--|
| Mode - SBAS Subsystem | Enabled / Disabled status of the SBAS subsystem. To |
| | enable/disable SBAS operation use UBX-CFG-GNSS. The field in |
| | UBX-CFG-SBAS is no longer supported. |
| Mode - Allow test mode usage | Allow / Disallow SBAS usage from satellites in Test Mode |
| | (Message 0) |
| Services/Usage - Ranging | Use the SBAS satellites for navigation |

SBAS Configuration parameters continued

| Parameter | Description |
|----------------------------------|---|
| Services/Usage - Apply SBAS | Combined enable/disable switch for Fast-, Long-Term and |
| correction data | Ionosphere Corrections |
| Services/Usage - Apply integrity | Use integrity data |
| information | |
| Number of tracking channels | Should be set using UBX-CFG-GNSS. The field in UBX-CFG-SBAS |
| | is no longer supported. |
| PRN Mask | Allows selectively enabling/disabling SBAS satellites (e.g. |
| | restrict SBAS usage to WAAS-only). |

By default, SBAS is enabled with three prioritized SBAS channels and it will use any received SBAS satellites (except for those in test mode) for navigation, ionosphere parameters and corrections.

6 QZSS L1S SLAS Configuration Settings Description

6.1 QZSS L1S SLAS (Sub-meter Level Augmentation Service)

The L1S signal was formerly known as L1SAIF.

QZSS SLAS (Sub-meter Level Augmentation Service) is an augmentation technology, which provides correction data for pseudoranges of GPS and QZSS satellites (as of October 2017). Ground monitoring stations (GMS) positioned in Japan calculate independent corrections for each visible satellite and broadcast this data to the user via QZSS satellites. The correction stream is transmitted on the L1 frequency (1575.42 Mhz) and therefore no additional receiver is required to make use of the correction data.

With QZSS SLAS enabled, u-blox receivers autonomously select the most suitable GMS based on the user's location. The correction stream of this GMS will then be applied to the measurements in order to improve position accuracy.

Furthermore, QZSS SLAS provides the user with reports for disaster and crisis management (DC Reports) from the Japan Meteorological Agency (JMA) and other sources. Those reports are provided by UBX-RXM-SFRBX messages.

For more information on QZSS SLAS, refer to the Interface Document IS-QZSS-L1S-001 (March 28, 2017) issued by the Cabinet Office, available from qzss.go.jp/en/.

6.2 QZSS L1S SLAS Features

Multiple SLAS signals can be tracked simultaneously. Only the number of receiver channels limits the total number of satellites tracked.

The correction stream will be automatically detected from the most suitable ground monitoring stations and QZSS satellites. The selection of the QZSS satellite is dependent on the quality of the signals and the receiver configuration to allow satellites in test mode. The GMS that is not flagged as unhealthy and is closest to the user will be selected. If the distance to the closest GMS exceeds 200 km, no corrections will be used. The receiver might then fall back to using SBAS corrections. Changes of the most suitable GMS or QZSS satellite as well as transitions in the provided correction data stream will be handled in the background leading to a continuous set of corrections for the navigation solution, if possible.

If corrections are available from the chosen QZSS satellite and used in the navigation calculation,

the DGNSS flag is set in the receiver's output protocol messages (see UBX-NAV-PVT, UBX-NAV-SOL, UBX-NAV-STATUS, UBX-NAV-SVINFO, NMEA Position Fix Flags description). The message UBX-NAV-SLAS provides detailed information about which corrections are available and applied.

By setting the RAIM feature (see UBX-CFG-SLAS), the user can setup the receiver to provide DGPS-only solutions or to mix corrected and uncorrected measurements.

If in UBX-CFG-SLAS the RAIM option is set, other GNSS time systems than the QZSS time system can't be observed by measurements.

Supported QZSS L1S SLAS messages for navigation enhancing

| Message Type | Message Content |
|--------------|--------------------------------|
| 0 | Test Mode |
| 47 | Monitoring Station Information |
| 48 | PRN Mask |
| 49 | Data Issue Number |
| 50 | DGPS Correction |
| 51 | Satellite Health |

6.3 QZSS L1S SLAS Configuration

To read and set the SLAS configurations use UBX-CFG-SLAS as follows:

QZSS L1S SLAS Configuration parameters

| Doromotor | Description |
|----------------|---|
| Parameter | Description |
| Mode - enabled | Apply QZSS SLAS corrections |
| Mode - test | Allow the correction provided by QZSS satellites that are in |
| | test mode |
| Mode - raim | If this configuration is set, the receiver will try to estimate the |
| | position by using only corrected measurements; if all corrected |
| | measurements are not available, it won't use any corrections. If |
| | this configuration is not set, the receiver will mix corrected and |
| | uncorrected measurements for the navigation solution. |

7 IMES Description

Indoor MEssaging System (IMES) is an extension to the QZSS specification using ground based beacons that broadcast their location. Its purpose is to allow GNSS users to continue to navigate inside buildings, when they can no longer reliably receive satellite based signals.

Operation of IMES beacons is only allowed within Japan.

u-blox receivers with IMES enabled conform to **IS-QZSS v1.5** and do not support v1.4 or earlier IMES signals. In particular, u-blox receivers rely on the IMES station's carrier frequency being 1575.4282MHz \(\mathbb{\text{M}} \) 0.2ppm as specified in the IMES specification. Transmissions from IMES stations that are not within this frequency range are unlikely to be reliably received. Also the receiver expects the preamble 0x9E as well as the correct sequence of CNT values as specified by the IS-QZSS.

u-blox receivers report the position information they receive from IMES transmitters directly with UBX-RXM-IMES. They do not, however, combine this information with navigation solutions derived from satellite signals (reported via various NMEA and UBX-NAV messages). Consequently, the

IMES position information may not always be consistent with satellite signal derived position information.

7.1 IMES Features

- 50/250bps Auto-Detection: Both 50bps and 250bps IMES signals are supported by u-blox receivers. The transmitter's data rate is detected automatically which allows the receiver to even work in a mixed 50bps/250bps IMES environment.
- Dynamic Tracking Channel Allocation: The allocation of the tracking channels is done dynamically, in the same way that channels are allocated to other GNSS. If sufficient IMES stations are within reach of the receiver, it will track as many signals as it can up to the value of maxTrkCh configured in UBX-CFG-GNSS (8 by default). To reserve a certain number of channels for IMES only (preventing them from being dynamically allocated to other GNSS), set the resTrkCh field in UBX-CFG-GNSS accordingly.
- **Data summary:** A summary of all the tracked IMES signals and what position information they are providing is given in the UBX-RXM-IMES message.
- Raw IMES frames: The raw IMES subframes received from the IMES stations are reported as they are received with UBX-RXM-SFRBX messages.

8 Navigation Configuration Settings Description

This section relates to the configuration message UBX-CFG-NAV5.

8.1 Platform settings

u-blox receivers support different dynamic platform models (see table below) to adjust the navigation engine to the expected application environment. These platform settings can be changed dynamically without performing a power cycle or reset. The settings improve the receiver's interpretation of the measurements and thus provide a more accurate position output. Setting the receiver to an unsuitable platform model for the given application environment is likely to result in a loss of receiver performance and position accuracy.

Dynamic Platform Models

| Platform | Description |
|--------------|---|
| Portable | Applications with low acceleration, e.g. portable devices. Suitable for most |
| | situations. |
| Stationary | Used in timing applications (antenna must be stationary) or other stationary |
| | applications. Velocity restricted to 0 m/s. Zero dynamics assumed. |
| Pedestrian | Applications with low acceleration and speed, e.g. how a pedestrian would move. |
| | Low acceleration assumed. |
| Automotive | Used for applications with equivalent dynamics to those of a passenger car. Low |
| | vertical acceleration assumed. |
| At sea | Recommended for applications at sea, with zero vertical velocity. Zero vertical |
| | velocity assumed. Sea level assumed. |
| Airborne <1g | Used for applications with a higher dynamic range and greater vertical |
| | acceleration than a passenger car. No 2D position fixes supported. |
| Airborne <2g | Recommended for typical airborne environments. No 2D position fixes |
| | supported. |

Dynamic Platform Models continued

| Platform | Description | |
|--------------|--|--|
| Airborne <4g | Only recommended for extremely dynamic environments. No 2D position fixes | |
| | supported. | |
| Wrist | Only recommended for wrist-worn applications. Receiver will filter out arm | |
| | motion (just available for protocol version > 17). | |
| Bike | Used for applications with equivalent dynamics to those of a motor bike. Low | |
| | vertical acceleration assumed. | |

Dynamic Platform Model Details

| Platform | Max Altitude | MAX Horizontal | MAX Vertical | Sanity check type | Max Position |
|--------------|--------------|----------------|----------------|-----------------------|--------------|
| | [m] | Velocity [m/s] | Velocity [m/s] | | Deviation |
| Portable | 12000 | 310 | 50 | Altitude and Velocity | Medium |
| Stationary | 9000 | 10 | 6 | Altitude and Velocity | Small |
| Pedestrian | 9000 | 30 | 20 | Altitude and Velocity | Small |
| Automotive | 6000 | 100 | 15 | Altitude and Velocity | Medium |
| At sea | 500 | 25 | 5 | Altitude and Velocity | Medium |
| Airborne <1g | 50000 | 100 | 100 | Altitude | Large |
| Airborne <2g | 50000 | 250 | 100 | Altitude | Large |
| Airborne <4g | 50000 | 500 | 100 | Altitude | Large |
| Wrist | 9000 | 30 | 20 | Altitude and Velocity | Medium |
| Bike | 6000 | 100 | 15 | Altitude and Velocity | Medium |

Dynamic platforms designed for high acceleration systems (e.g. airborne <2g) can result in a higher standard deviation in the reported position.

If a sanity check against a limit of the dynamic platform model fails, then the position solution is invalidated. The table above shows the types of sanity checks which are applied for a particular dynamic platform model.

8.2 Navigation Input Filters

The navigation input filters in UBX-CFG-NAV5 mask the input data of the navigation engine.

These settings are already optimized. Do not change any parameters unless advised by u-blox support engineers.

Navigation Input Filter parameters

| Parameter | Description | | | |
|--------------|---|--|--|--|
| fixMode | By default, the receiver calculates a 3D position fix if possible but reverts to 2D | | | |
| | position if necessary (Auto 2D/3D). The receiver can be forced to only calculate | | | |
| | 2D (2D only) or 3D (3D only) positions. | | | |
| fixedAlt and | The fixed altitude is used if fixMode is set to 2D only. A variance greater than | | | |
| fixedAltVar | zero must also be supplied. | | | |
| minElev | Minimum elevation of a satellite above the horizon in order to be used in the | | | |
| | navigation solution. Low elevation satellites may provide degraded accuracy, | | | |
| | due to the long signal path through the atmosphere. | | | |
| cnoThreshNum | A navigation solution will only be attempted if there are at least the given | | | |
| SVs and | number of SVs with signals at least as strong as the given threshold. | | | |
| cnoThresh | | | | |

See also comments in section Degraded Navigation below.

8.3 Navigation Output Filters

The result of a navigation solution is initially classified by the fix type (as detailed in the fixType field of UBX-NAV-PVT message). This distinguishes between failures to obtain a fix at all ("No Fix") and cases where a fix has been achieved, which are further subdivided into specific types of fixes (e.g. 2D, 3D, dead reckoning).

Where a fix has been achieved, a check is made to determine whether the fix should be classified as valid or not. A fix is only valid if it passes the navigation output filters as defined in UBX-CFG-NAV5. In particular, both PDOP and accuracy values must lie below the respective limits.

Valid fixes are marked using the valid flag in certain NMEA messages (see Position Fix Flags in NMEA) and the gnssFixOK flag in UBX-NAV-PVT message.

Important: Users are recommended to check the gnssFixOK flag in the UBX-NAV-PVT or the NMEA valid flag. Fixes not marked valid should not normally be used.

The UBX-NAV-SOL and UBX-NAV-STATUS messages also report whether a fix is valid in their gpsFixOK and GPSfixOk flags. These messages have only been retained for backwards compatibility and users are recommended to use the UBX-NAV-PVT message in preference.

The UBX-CFG-NAV5 message also defines TDOP and time accuracy values that are used in order to establish whether a fix is regarded as locked to GNSS or not, and as a consequence of this, which time pulse setting has to be used. Fixes that do not meet both criteria will be regarded as unlocked to GNSS, and the corresponding time pulse settings of UBX-CFG-TP5 will be used to generate a time pulse.

8.3.1 Speed (3-D) Low-pass Filter

The UBX-CFG-ODO message offers the possibility to activate a speed (3-D) low-pass filter. The output of the speed low-pass filter is published in the UBX-NAV-VELNED message (speed field). The filtering level can be set via the UBX-CFG-ODO message (vellpGain field) and must be comprised between 0 (heavy low-pass filtering) and 255 (weak low-pass filtering).

The internal filter gain is computed as a function of speed. Therefore, the level as defined in the UBX-CFG-ODO message (velLpGain field) defines the nominal filtering level for speeds below 5m/s.

8.3.2 Course over Ground Low-pass Filter

The UBX-CFG-ODO message offers the possibility to activate a course over ground low-pass filter when the speed is below 8m/s. The output of the course over ground (also named heading of motion 2-D) low-pass filter is published in the UBX-NAV-PVT message (headMot field), UBX-NAV-VELNED message (heading field), NMEA-RMC message (cog field) and NMEA-VTG message (cogt field). The filtering level can be set via the UBX-CFG-ODO message (cogLpGain field) and must be comprised between 0 (heavy low-pass filtering) and 255 (weak low-pass filtering).

The filtering level as defined in the UBX-CFG-ODO message (cogLpGain field) defines the filter gain for speeds below 8m/s. If the speed is higher than 8m/s, no course over ground low-pass filtering is performed.

8.3.3 Low-speed Course Over Ground Filter

The UBX-CFG-ODO message offers the possibility to activate a low-speed course over ground filter (also called heading of motion 2-D). This filter derives the course over ground from position at very low speed. The output of the low-speed course over ground filter is published in the UBX-NAV-PVT message (headMot field), UBX-NAV-VELNED message (heading field), NMEA-RMC message (cog field) and NMEA-VTG message (cogt field). If the low-speed course over ground filter is not activated or inactive, then the course over ground is computed as described in section Freezing the Course Over Ground.

8.4 Static Hold

Static Hold Mode allows the navigation algorithms to decrease the noise in the position output when the velocity is below a pre-defined 'Static Hold Threshold'. This reduces the position wander caused by environmental factors such as multi-path and improves position accuracy especially in stationary applications. By default, static hold mode is disabled.

If the speed drops below the defined 'Static Hold Threshold, the Static Hold Mode will be activated. Once Static Hold Mode has been entered, the position output is kept static and the velocity is set to zero until there is evidence of movement again. Such evidence can be velocity, acceleration, changes of the valid flag (e.g. position accuracy estimate exceeding the Position Accuracy Mask, see also section Navigation Output Filters), position displacement, etc.

The UBX-CFG-NAV5 message additionally allows for configuration of distance threshold (field staticHoldMaxDist). If the estimated position is farther away from the static hold position than this threshold, static mode will be quit.

8.5 Freezing the Course Over Ground

If the low-speed course over ground filter is deactivated or inactive (see section Low-speed Course over Ground Filter), the receiver derives the course over ground from the GNSS velocity information. If the velocity cannot be calculated with sufficient accuracy (e.g., with bad signals) or if the absolute speed value is very low (under 0.1m/s) then the course over ground value becomes inaccurate too. In this case the course over ground value is frozen, i.e. the previous value is kept and its accuracy is degraded over time. These frozen values will not be output in the NMEA messages NMEA-RMC and NMEA-VTG unless the NMEA protocol is explicitly configured to do so (see NMEA Protocol Configuration).

8.6 Degraded Navigation

Degraded navigation describes all navigation modes which use less than four Satellite Vehicles (SV).

8.6.1 2D Navigation

If the receiver only has three SVs for calculating a position, the navigation algorithm uses a constant altitude to compensate for the missing fourth SV. When an SV is lost after a successful 3D fix (min. four SVs available), the altitude is kept constant at the last known value. This is called a 2D fix.

u-blox receivers do not calculate any navigation solution with less than three SVs. Only u-blox Timing products can calculate a timing solution with only one SV when they are in stationary mode.

8.7 Geodetic Coordinate Systems and Ellipsoids

In order to have any useful meaning, the positions reported by a u-blox receiver must be referenced to some coordinate system which defines the origin and, for example, which way is "up". For many reasons, including history, practical autonomy and politics, all the major GNSS define their own theoretical coordinate systems from which they realize a practical reference frame by means of a network of reference points. Specifically:

- GPS uses WGS84
- GLONASS uses PZ90
- · Galileo uses GTRF
- BeiDou uses CGCS2000

In practice, the relevant organisations choose to keep their respective frames very close to the International Terrestrial Reference Frame (ITRF), defined and managed by the International Earth Rotation and Reference Systems Service (IERS). However, because the Earth's tectonic plates and even parts of the Earth's core move, new versions of ITRF are defined every few years, generally with changes of the order of a few millimetres. Consequently, the major GNSS occasionally decide that they need to update their reference frames to be better aligned to the latest ITRF. So, for example, GPS switched to WGS84 (G1150) in GPS week 1150 (early 2002) based on ITRF2000, while GLONASS switched from PZ90.02 to PZ90.11 at the end of 2013, based on ITRF2008. The net effect of this, is that all the major GNSS use almost the same reference frame, but there are some small (generally sub-cm) differences between them and these differences occasionally change.

In order to produce positions that can be shown on a map, it is necessary to translate between raw coordinates (e.g. x, y, z) and a position relative to the Earth's surface (e.g. latitude, longitude and altitude) and that requires defining the form of ellipsoid that best matches the shape of the Earth. Historically many different ellipsoid definitions have been used for maps, many of which predate the existence of GNSS and show quite significant differences, leading to discrepencies of as much as 100 m in places. Fortunately, most digital maps now use the WGS84 ellipsoid, which is distinct from the WGS84 coordinate system, but defined by the same body.

All u-blox receivers use (the current) version of WGS84 frame as their reference frame, carrying out any necessary corrections internally. What is more, by default, u-blox receivers use the WGS84 ellipsoid and therefore all positions communicated from/to a u-blox receiver will be relative to that. However, users can alter this by specifying their chosen geodetic datum parameters using the UBX-CFG-DAT message. The table below indicates the values u-blox recommends for use.

Recommended UBX-CFG-DAT parameters

| | <u> </u> | | | | | | | |
|-----------------|-----------|---------------|-----|-----|-----|------|------|------|
| Ellipsoid | majA | flat | dX | dY | dZ | rotX | rotY | rotZ |
| WGS84 (default) | 6378137.0 | 298.257223563 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 |
| PZ90 | 6378136.0 | 298.257839303 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 |
| CGCS2000 | 6378137.0 | 298.257227101 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 |

Where the receiver is configured to use differential correction data (e.g. via an RTCM stream), as a direct consequence, the receiver's coordinate frame will switch to whatever frame the source of correction data is using.

9 Clocks and Time

9.1 Receiver Local Time

The receiver is dependent on a local oscillator (normally a TCXO or Crystal oscillator) for both the operation of its radio parts and also for timing within its signal processing. No matter what nominal frequency the local oscillator has (e.g. 26 MHz), u-blox receivers subdivide the oscillator signal to provide a 1 kHz reference clock signal, which is used to drive many of the receiver's processes. In particular, the measurement of satellite signals is arranged to be synchronised with the "ticking" of this 1 kHz clock signal.

When the receiver first starts, it has no information about how these clock ticks relate to other time systems; it can only count time in 1 millisecond steps. However, as the receiver derives information from the satellites it is tracking or from aiding messages, it estimates the time that each 1 kHz clock tick takes in the time-base of the relevant GNSS system. In previous generations of u-blox receivers this was always the GPS time-base, but for this generation it could be GPS, GLONASS, Galileo, or BeiDou. This estimate of GNSS time based on the local 1 kHz clock is called receiver local time.

As receiver local time is a mapping of the local 1 kHz reference onto a GNSS time-base, it may experience occasional discontinuities, especially when the receiver first starts up and the information it has about the time-base is changing. Indeed after a cold start receiver local time will initially indicate the length of time that the receiver has been running. However, when the receiver obtains some credible timing information from a satellite or aiding message, it will jump to an estimate of GNSS time.

9.2 Navigation Epochs

Each navigation solution is triggered by the tick of the 1 kHz clock nearest to the desired navigation solution time. This tick is referred to as a **navigation epoch**. If the navigation solution attempt is successful, one of the results is an accurate measurement of time in the time-base of the chosen GNSS system, called **GNSS system time**. The difference between the calculated GNSS system time and receiver local time is called the **clock bias** (and the **clock drift** is the rate at which this bias is changing).

In practice the receiver's local oscillator will not be as stable as the atomic clocks to which GNSS systems are referenced and consequently clock bias will tend to accumulate. However, when selecting the next navigation epoch, the receiver will always try to use the 1 kHz clock tick which it estimates to be closest to the desired fix period as measured in GNSS system time. Consequently the number of 1 kHz clock ticks between fixes will occasionally vary (so when producing one fix per second, there will normally be 1000 clock ticks between fixes, but sometimes, to correct drift away from GNSS system time, there will be 999 or 1001).

The GNSS system time calculated in the navigation solution is always converted to a time in both the GPS and UTC time-bases for output.

Clearly when the receiver has chosen to use the GPS time-base for its GNSS system time, conversion to GPS time requires no work at all, but conversion to UTC requires knowledge of the number of leap seconds since GPS time started (and other minor correction terms). The relevant GPS to UTC conversion parameters are transmitted periodically (every 12.5 minutes) by GPS satellites, but can also be supplied to the receiver via the UBX-MGA-GPS-UTC aiding message. By contrast when the receiver has chosen to use the GLONASS time-base as its GNSS system time,

conversion to GPS time is more difficult as it requires knowledge of the difference between the two time-bases, but conversion to UTC is easier (as GLONASS time is closely linked to UTC).

Where insufficient information is available for the receiver to perform any of these time-base conversions precisely, pre-defined default offsets are used. Consequently plausible times are nearly always generated, but they may be wrong by a few seconds (especially shortly after receiver start). Depending on the configuration of the receiver, such "invalid" times may well be output, but with flags indicating their state (e.g. the "valid" flags in UBX-NAV-PVT).

u-blox receivers employ multiple GNSS system times and/or receiver local times (in order to support multiple GNSS systems concurrently), so users should not rely on UBX messages that report GNSS system time or receiver local time being supported in future. It is therefore recommended to give preference to those messages that report UTC time.

9.3 iTOW Timestamps

All the main UBX-NAV messages (and some other messages) contain an **iTOW** field which indicates the GPS time at which the navigation epoch occurred. Messages with the same iTOW value can be assumed to have come from the same navigation solution.

Note that iTOW values may not be valid (i.e. they may have been generated with insufficient conversion data) and therefore it is not recommended to use the iTOW field for any other purpose.

The original designers of GPS chose to express time/date as an integer week number (starting with the first full week in January 1980) and a time of week (often abbreviated to TOW) expressed in seconds. Manipulating time/date in this form is far easier for digital systems than the more "conventional" year/month/day, hour/minute/second representation. Consequently, most GNSS receivers use this representation internally, only converting to a more "conventional form" at external interfaces. The iTOW field is the most obvious externally visible consequence of this internal representation.

If reliable absolute time information is required, users are recommended to use the UBX-NAV-PVT or UBX-HNR-PVT navigation solution messages which also contain additional fields that indicate the validity (and accuracy in UBX-NAV-PVT) of the calculated times (see also the GNSS Times section below for further messages containing time information).

9.4 GNSS Times

Each GNSS has its own time reference for which detailed and reliable information is provided in the messages listed in the table below.

GNSS Times

| Time Reference | Message |
|----------------|-----------------|
| GPS Time | UBX-NAV-TIMEGPS |
| BeiDou Time | UBX-NAV-TIMEBDS |
| GLONASS Time | UBX-NAV-TIMEGLO |
| Galileo Time | UBX-NAV-TIMEGAL |
| UTC Time | UBX-NAV-TIMEUTC |

9.5 Time Validity

Information about the validity of the time solution is given in the following form:

- Time validity: Information about time validity is provided in the valid flags (e.g. validDate and validTime flags in the UBX-NAV-PVT message). If these flags are set, the time is known and considered as valid for being used. These flags can be found in the GNSS Times table in the GNSS Times section above as well as in the UBX-NAV-PVT and UBX-HNR-PVT messages.
- Time validity confirmation: Information about confirmed validity is provided in the confirmedDate and confirmedTime flags in the UBX-NAV-PVT message. If these flags are set, the time validity could be confirmed by using an additional independent source, meaning that the probability of the time to be correct is very high. Note that information about time validity confirmation is only available if the confirmedAvai bit in the UBX-NAV-PVT message is set. Check UBX-NAV-PVT which Protocol Version supports this flag.

9.6 UTC Representation

UTC time is used in many NMEA and UBX messages. In NMEA messages it is always reported rounded to the nearest hundredth of a second. Consequently, it is normally reported with two decimal places (e.g. 124923.52). What is more, although compatibility mode (selected using UBX-CFG-NMEA) requires three decimal places, rounding to the nearest hundredth of a second remains, so the extra digit is always 0.

UTC time is is also reported within some UBX messages, such as UBX-NAV-TIMEUTC and UBX-NAV-PVT. In these messages date and time are separated into seven distinct integer fields. Six of these (year, month, day, hour, min and sec) have fairly obvious meanings and are all guaranteed to match the corresponding values in NMEA messages generated by the same navigation epoch. This facilitates simple synchronisation between associated UBX and NMEA messages.

The seventh field is called nano and it contains the number of nanoseconds by which the rest of the time and date fields need to be corrected to get the precise time. So, for example, the UTC time 12:49:23.521 would be reported as: hour: 12, min: 49, sec: 23, nano: 521000000.

It is however important to note that the first six fields are the result of rounding to the nearest hundredth of a second. Consequently the nano value can range from -5000000 (i.e. -5 ms) to +99499999 (i.e. nearly 995 ms).

When the nano field is negative, the number of seconds (and maybe minutes, hours, days, months or even years) will have been rounded up. Therefore, some or all of them will need to be adjusted in order to get the correct time and date. Thus in an extreme example, the UTC time 23:59:59.9993 on 31st December 2011 would be reported as: year: 2012, month: 1, day: 1, hour: 0, min: 0, sec: 0, nano: -700000.

Of course, if a resolution of one hundredth of a second is adequate, negative nano values can simply be rounded up to 0 and effectively ignored.

Which master clock the UTC time is referenced to is output in the message UBX-NAV-TIMEUTC. For protocol versions 16 or greater, the preferred variant of UTC time can be specified using UBX-CFG-NAV5.

9.7 Leap Seconds

Occasionally it is decided (by one of the international time keeping bodies) that, due to the slightly uneven spin rate of the Earth, UTC has moved sufficiently out of alignment with mean solar time (i.e. the Sun no longer appears directly overhead at 0 longitude at midday). A "leap second" is

therefore announced to bring UTC back into close alignment. This normally involves adding an extra second to the last minute of the year, but it can also happen on 30th June. When this happens UTC clocks are expected to go from 23:59:59 to 23:59:60 and only then on to 00:00:00.

It is also theoretically possible to have a negative leap second, in which case there will only be 59 seconds in a minute and 23:59:58 will be followed by 00:00:00.

u-blox receivers are designed to handle leap seconds in their UTC output and consequently users processing UTC times from either NMEA and UBX messages should be prepared to handle minutes that are either 59 or 61 seconds long.

Leap second information be be polled from the u-blox receiver with the message UBX-NAV-TIMELS for Protocol Version 18 and above.

9.8 Real Time Clock

u-blox receivers contain circuitry to support a **real time clock**, which (if correctly fitted and powered) keeps time while the receiver is otherwise powered off. When the receiver powers up, it attempts to use the real time clock to initialise receiver local time and in most cases this leads to appreciably faster first fixes.

9.9 Date

All GNSS frequently transmit information about the current time within their data message. In most cases, this is a time of week (often abbreviated to TOW), which indicates the elapsed number of seconds since the start of the week (midnight Saturday/Sunday). In order to map this to a full date, it is necessary to know which week and so the GNSS also transmit a week number, typically every 30 seconds. Unfortunately the GPS data message was designed in a way that only allows the bottom 10 bits of the week number to be transmitted. This is not sufficient to yield a completely unambiguous date as every 1024 weeks (a bit less than 20 years), the transmitted week number value "rolls over" back to zero. Consequently, GPS receivers can't tell the difference between, for example, 1980, 1999 or 2019 etc.

Fortunately, although BeiDou and Galileo have similar representations of time, they transmit sufficient bits for the week number to be unambiguous for the forseeable future (the first ambiguity will be in 2078 for Galileo and not until 2163 for BeiDou). GLONASS has a different structure, based on a time of day, but again transmits sufficient information to avoid any ambiguity during the expected lifetime of the system (the first ambiguous date will be in 2124). Therefore, u-blox 8 / u-blox M8 receivers using Protocol Version 18 and above regard the date information transmitted by GLONASS, BeiDou and Galileo to be unambiguous and, where necessary, use this to resolve any ambiguity in the GPS date.

Customers attaching u-blox receivers to simulators should be aware that GPS time is referenced to 6th January 1980, GLONASS to 1st January 1996, Galileo to 22nd August 1999 and BeiDou to 1st January 2006; the receiver cannot be expected to work reliably with signals that appear to come from before these dates.

9.9.1 GPS-only Date Resolution

In circumstances where only GPS signals are available and for receivers with earlier firmware versions, the receiver establishes the date by assuming that all week numbers must be at least as large as a reference rollover week number. This reference rollover week number is hard-coded into the firmware at compile time and is normally set a few weeks before the s/w is completed, but it can be overridden by the wknRollover field of the UBX-CFG-NAVX5 message to any value the user

wishes.

The following example illustrates how this works: Assume that the reference rollover week number set in the firmware at compile time is 1524 (which corresponds to a week in calendar year 2009, but would be transmitted by the satellites as 500). In this case, if the receiver sees transmissions containing week numbers in the range 500 ... 1023, these will be interpreted as week numbers 1524 ... 2047 (CY 2009 ... 2019), whereas transmissions with week numbers from 0 to 499 are interpreted as week numbers 2048 ... 2547 (CY 2019 ... 2028).

It is important to set the reference rollover week number appropriately when supplying ublox receivers with simulated signals, especially when the scenarios are in the past.

10 Broadcast Navigation Data

Reporting of broadcast navigation data is supported for products using protocol version 17 onwards.

The UBX-RXM-SFRBX reports the broadcast navigation data message collected by the receiver from each tracked signal. When enabled, a separate message is generated every time the receiver decodes a complete subframe of data from a tracked signal. The data bits are reported, as received, including preambles and error checking bits as appropriate. However because there is considerable variation in the data structure of the different GNSS signals, the form of the reported data also varies. Indeed, although this document uses the term "subframe" generically, it is not strictly the correct term for all GNSS (e.g. GLONASS has "strings" and Galileo has "pages").

10.1 Parsing Navigation Data Subframes

Each UBX-RXM-SFRBX message contains a subframe of data bits appropriate for the relevant GNSS, delivered in a number of 32 bit words, as indicated by numWords field.

Due to the variation in data structure between different GNSS, the most important step in parsing a UBX-RXM-SFRBX message is to identify the form of the data. This should be done by reading the gnssId field, which indicates which GNSS the data was decoded from. In almost all cases, this is sufficient to indicate the structure and the following sections are organised by GNSS for that reason. However, in some cases the identity of the GNSS is not sufficient, and this is described, where appropriate, in the following sections.

In most cases, the data does not map perfectly into a number of 32 bit words and, consequently, some of the words reported in UBX-RXM-SFRBX messages contain fields marked as "Pad". These fields should be ignored and no assumption should be made about their contents.

UBX-RXM-SFRBX messages are only generated when complete subframes are detected by the receiver and all appropriate parity checks have passed.

Where the parity checking algorithm requires data to be inverted before it is decoded (e.g. GPS L1C/A), the receiver carries this out before the message output. Therefore, users can process data directly and do not need to worry about repeating any parity processing.

The meaning of the content of each subframe depends on the sending GNSS and is described in the relevant Interface Control Documents (ICD).

10.2 GPS

The data structure in the GPS L1C/A and L2C signals is dissimilar and thus the UBX-RXM-SFRBX message structure differs as well. For the GPS L1C/A and L2C signals it is as follows.

10.2.1 GPS L1C/A

For GPS L1C/A signals, there is a fairly straightforward mapping between the reported subframe and the structure of subframe and words described in the GPS ICD. Each subframe comprises ten data words, which are reported in the same order they are received.

Each word is arranged as follows:

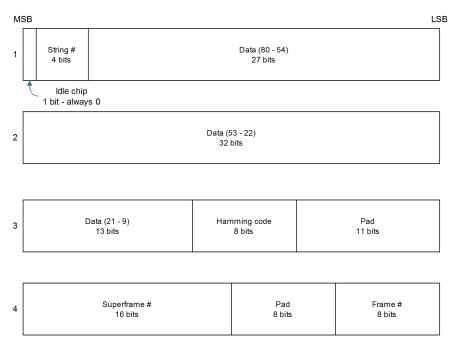

Note that as the GPS data words only comprise 30 bits, the 2 most significant bits in each word reported by UBX-RXM-SFRBX are padding and should be ignored.

10.3 GLONASS

For GLONASS L10F and L20F signals, each reported subframe contains a string as described in the GLONASS ICD. This string comprises 85 data bits which are reported over three 32 bit words in the UBX-RXM-SFRBX message. Data bits 1 to 8 are always a hamming code, whilst bits 81 to 84 are a string number and bit 85 is the idle chip, which should always have a value of zero. The meaning of other bits vary with string and frame number.

The fourth and final 32 bit word in the UBX-RXM-SFRBX message contains frame and superframe numbers (where available). These values aren't actually transmitted by the SVs, but are deduced by the receiver and are included to aid decoding of the transmitted data. However, the receiver does not always know these values, in which case a value of zero is reported.

The four words are arranged as follows:

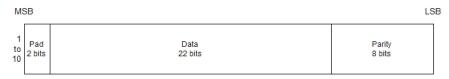

In some circumstances, (especially on startup) the receiver may be able to decode data from a GLONASS SV before it can identify the SV. When this occurs UBX-RXM-SFRBX messages will be issued with an svId of 255 to indicate "unknown".

10.4 BeiDou

For BeiDou (B1I) signals, there is a fairly straightforward mapping between the reported subframe and the structure of subframe and words described in the BeiDou ICD. Each subframe comprises ten data words, which are reported in the same order they are received.

Each word is arranged as follows:

Note that as the BeiDou data words only comprise 30 bits, the 2 most significant bits in each word reported by UBX-RXM-SFRBX are padding and should be ignored.

10.5 Galileo

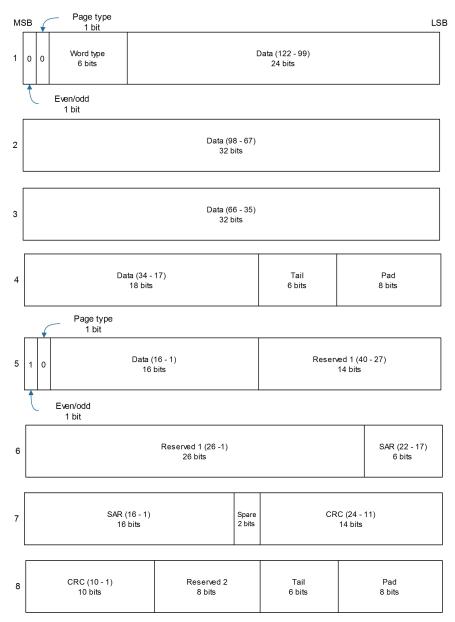

The Galileo E1OS and E5b signals both transmit the I/NAV message but in different configurations. The UBX-RXM-SFRBX structures for them are as follows.

10.5.1 Galileo E1OS

For Galileo E1OS signals, each reported subframe contains a pair of I/NAV pages as described in the Galileo ICD.

Galileo pages can either be "Nominal" or "Alert" pages. For Nominal pages the eight words are arranged as follows:

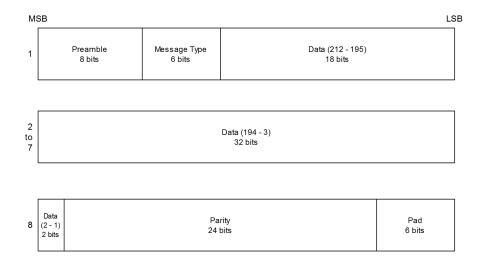

Alert pages are reported in very similar manner, but the page type bits will have value 1 and the structure of the eight words will be slightly different (as indicated by the Galileo ICD).

10.6 SBAS

For SBAS (L1C/A) signals each reported subframe contains eight 32 data words to deliver the 250 bits transmitted in each SBAS data block.

The eight words are arranged as follows:

10.7 QZSS

The structure of the data delivered by QZSS L1C/A signals is effectively identical to that of GPS (L1C/A). Similarly the QZSS L2C signal is effectively identical to the GPS (L2C).

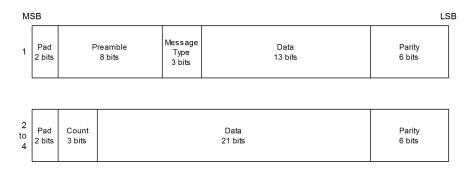

The QZSS (L1SAIF) signal is different and uses the same data block format as used by SBAS (L1C/A). QZSS (SAIF) signals can be distinguished from QZSS (L1C/A and L2C) by noting that they have 8 words, instead of 10 for QZSS (L1C/A and L2C).

10.8 IMES

Data messages from IMES are of variable length and u-blox receivers currently support the following varieties:

- · Short comprising of a single word
- · Medium comprising of two words
- Position 1 comprising of three words
- Position 2 comprising of four words

As a consequence, an IMES UBX-RXM-SFRBX message may have a numWords value of 1, 2, 3 or 4. In all cases the structure of words follows the same pattern, with the first word being different from any/all subsequent words as indicated by the following diagram:

10.9 Summary

The following table gives a summary of the different data message formats reported by the UBX-RXM-SFRBX message.

| GNSS | Signal | gnssld | numWords | period |
|---------|------------|--------|----------|--------|
| GPS | L1C/A | 0 | 10 | 6s |
| SBAS | L1C/A | 1 | 8 | 1s |
| Galileo | E1OS | 2 | 8 | 2s |
| BeiDou | B1I D1 | 3 | 10 | 6s |
| BeiDou | B1I D2 | 3 | 10 | 0.6s |
| IMES | Short | 4 | 1 | _ |
| IMES | Medium | 4 | 2 | _ |
| IMES | Position 1 | 4 | 3 | - |
| IMES | Position 2 | 4 | 4 | - |
| QZSS | L1C/A | 5 | 10 | 6s |
| QZSS | L1SAIF | 5 | 8 | 1s |
| GLONASS | L10F | 6 | 4 | 2s |

11 Serial Communication Ports Description

u-blox receivers come with a highly flexible communication interface. It supports the NMEA and the proprietary UBX protocols, and is truly multi-port and multi-protocol capable. Each protocol (UBX, NMEA) can be assigned to several ports at the same time (multi-port capability) with individual settings (e.g. baud rate, message rates, etc.) for each port. It is even possible to assign more than one protocol (e.g. UBX protocol and NMEA at the same time) to a single port (multi-protocol capability), which is particularly useful for debugging purposes.

To enable a message on a port, the UBX and/or NMEA protocol must be enabled on that port using the UBX proprietary message UBX-CFG-PRT. This message also allows changing port-specific settings (baud rate, address etc.). See UBX-CFG-MSG for a description of the mechanism for enabling and disabling messages.

The following table shows the port numbers reported in the messages <code>UBX-MON-IO</code>, <code>UBX-MON-MSGPP</code>, <code>UBX-MON-TXBUF</code>, <code>UBX-MON-RXBUF</code>. Note that any numbers not listed are reserved for future use.

Port Number assignment

| Port # | Electrical Interface |
|--------|----------------------|
| 0 | DDC (I2C compatible) |
| 1 | UART 1 |
| 3 | USB |
| 4 | SPI |

11.1 TX-ready indication

This feature enables each port to define a corresponding pin, which indicates if bytes are ready to be transmitted. By default, this feature is disabled. For USB, this feature is configurable but might not behave as described below due to a different internal transmission mechanism. If the number of pending bytes reaches the threshold configured for this port, the corresponding pin will become active (configurable active-low or active-high), and stay active until the last bytes have been transferred from software to hardware (note that this is not necessarily equal to all bytes transmitted, i.e. after the pin has become inactive, up to 16 bytes can still need to be transferred to the host).

The TX-ready pin can be selected from all PIOs which are not in use (see UBX-MON-HW for a list of the PIOs and their mapping), each TX-ready pin is exclusively for one port and cannot be shared. If the PIO is invalid or already in use, only the configuration for the TX-ready pin is ignored, the rest of the port configuration is applied if valid. The acknowledge message does not indicate if the TX-ready configuration is successfully set, it only indicates the successful configuration of the port. To validate successful configuration of the TX-ready pin, the port configuration should be polled and the settings of TX-ready feature verified (will be set to disabled/all zero if the settings are invalid).

The threshold should not be set above 2 kB, as the internal message buffer limit can be reached before this, resulting in the TX-ready pin never being set as messages are discarded before the threshold is reached.

11.2 Extended TX timeout

If the host does not communicate over SPI or DDC for more than approximately 2 seconds, the device assumes that the host is no longer using this interface and no more packets are scheduled for this port. This mechanism can be changed by enabling "extended TX timeouts", in which case the receiver delays idling the port until the allocated and undelivered bytes for this port reach 4 kB. This feature is especially useful when using the TX-ready feature with a message output rate of less than once per second, and polling data only when data is available, determined by the TX-ready pin becoming active.

11.3 UART Ports

One or two Universal Asynchronous Receiver/Transmitter (UART) ports are featured, that can be used to transmit GNSS measurements, monitor status information and configure the receiver. See our online product descriptions for availability.

The serial ports consist of an RX and a TX line. Neither handshaking signals nor hardware flow control signals are available. These serial ports operate in asynchronous mode. The baud rates can be configured individually for each serial port. However, there is no support for setting different baud rates for reception and transmission.

As of Protocol version 18+, the UART RX interface will be disabled when more than 100 frame errors are detected during a one-second period. This can happen if the wrong baud rate is used or the UART RX pin is grounded. The error message appears when the UART RX interface is re-enabled at the end of the one-second period.

Possible UART Interface Configurations

| Baud Rate | Data Bits | Parity | Stop Bits |
|-----------|-----------|--------|-----------|
| 4800 | 8 | none | 1 |
| 9600 | 8 | none | 1 |
| 19200 | 8 | none | 1 |
| 38400 | 8 | none | 1 |
| 57600 | 8 | none | 1 |
| 115200 | 8 | none | 1 |
| 230400 | 8 | none | 1 |
| 460800 | 8 | none | 1 |

Note that for protocols such as NMEA or UBX, it does not make sense to change the default word length values (data bits) since these properties are defined by the protocol and not by the

electrical interface.

If the amount of data configured is too much for a certain port's bandwidth (e.g. all UBX messages output on a UART port with a baud rate of 9600), the buffer will fill up. Once the buffer space is exceeded, new messages to be sent will be dropped. To prevent message losses, the baud rate and communication speed or the number of enabled messages should be selected so that the expected number of bytes can be transmitted in less than one second.

See UBX-CFG-PRT for UART for a description of the contents of the UART port configuration message.

11.4 USB Port

One Universal Serial Bus (USB) port is featured. See the data sheet for availability. This port can be used for communication purposes and to power the positioning chip or module.

The USB interface supports two different power modes:

- In Self Powered Mode the receiver is powered by its own power supply. VDDUSB is used to detect the availability of the USB port, i.e. whether the receiver is connected to a USB host.
- In Bus Powered Mode the device is powered by the USB bus, therefore no additional power supply is needed. See the table below for the default maximum current that can be drawn by the receiver. See UBX-CFG-USB for a description on how to change this maximum. Configuring Bus Powered Mode indicates that the device will enter a low power state with disabled GNSS functionality when the host suspends the device, e.g. when the host is put into stand-by mode.

Maximum Current in Bus Powered Mode

| Generation | Max Current |
|----------------------|-------------|
| u-blox 8 / u-blox M8 | 100 mA |

The voltage range for **VDDUSB** is specified from 3.0 V to 3.6 V, which differs slightly from the specification for VCC.

The boot screen is retransmitted on the USB port after the enumeration. However, messages generated between boot-up of the receiver and USB enumeration are not visible on the USB port.

11.5 DDC Port

The Display Data Channel (DDC) bus is a two-wire communication interface compatible with the I2C standard (Inter-Integrated Circuit). See our online product selector matrix for availability.

Unlike all other interfaces, the DDC is not able to communicate in full-duplex mode, i.e. TX and RX are mutually exclusive. u-blox receivers act as a slave in the communication setup, therefore they cannot initiate data transfers on their own. The host, which is always master, provides the data clock (SCL), and the clock frequency is therefore not configurable on the slave.

The receiver's DDC address is set to 0x42 by default. This address can be changed by setting the mode field in UBX-CFG-PRT for DDC accordingly.

As the receiver will be run in slave mode and the DDC physical layer lacks a handshake mechanism to inform the master about data availability, a layer has been inserted between the physical layer and the UBX and NMEA layer. The receiver DDC interface implements a simple streaming interface that allows the constant polling of data, discarding everything that is not parse-able. The receiver returns 0xFF if no data is available. The TX-ready feature can be used to inform the master about data availability and can be used as a trigger for data transmission.

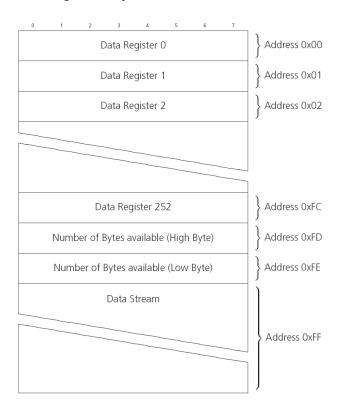

11.5.1 Read Access

The DDC interface allows 256 slave registers to be addressed. As shown in Figure DDC Register Layout only three of these are currently implemented. The data registers 0 to 252, at addresses 0x00 to 0xFC, each 1 byte in size, contain information to be defined later - the result of reading them is undefined. The currently available number of bytes in the message stream can be read at addresses 0xFD and 0xFE. The register at address 0xFF allows the data stream to be read. If there is no data awaiting transmission from the receiver, then this register will deliver the value 0xff, which cannot be the first byte of a valid message. If message data is ready for transmission, then successive reads of register 0xff will deliver the waiting message data.

The registers 0x00 to 0xFC are reserved for future use and may be defined in a later firmware release. Do not use them, as they don't provide any meaningful data!

DDC Register Layout

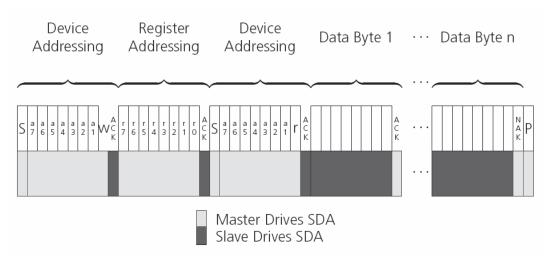

11.5.1.1 Read Access Forms

There are two forms of DDC read transfer. The 'random access' form includes a slave register address and thus allows any register to be read. The second 'current address' form omits the register address. If this second form is used, then an address pointer in the receiver is used to determine which register to read. This address pointer will increment after each read unless it is already pointing at register 0xff, the highest addressable register, in which case it remains unaltered. The initial value of this address pointer at start-up is 0xff, so by default all current address reads will repeatedly read register 0xff and receive the next byte of message data (or 0xff if no message data is waiting). Figure DDC Random Read Access shows the format of the random access form of the request. Following the start condition from the master, the 7-bit device address and the RW bit (which is a logic low for write access) are clocked onto the bus by the master transmitter. The receiver answers with an acknowledge (logic low) to indicate that it

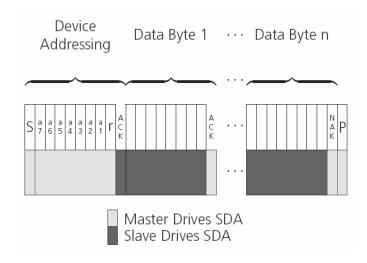

recognises the address. Next, the 8-bit address of the register to be read must be written to the bus. Following the receiver's acknowledge, the master again triggers a start condition and writes the device address, but this time the RW bit is a logic high to initiate the read access. Now, the master can read 1 to N bytes from the receiver, generating a not-acknowledge and a stop condition after the last byte being read.

DDC Random Read Access

The format of the current address read request is:

DDC Current Address Read Access

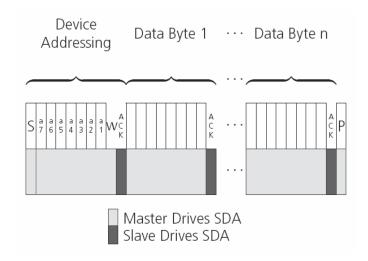

11.5.2 Write Access

The receiver does not provide any write access except for writing UBX and NMEA messages to the receiver, such as configuration or aiding data. Therefore, the register set mentioned in section Read Access is not writeable. Following the start condition from the master, the 7-bit device address and the RW bit (which is a logic low for write access) are clocked onto the bus by the master transmitter. The receiver answers with an acknowledge (logic low) to indicate that it is responsible for the given address. Now, the master can write 2 to N bytes to the receiver, generating a stop condition after the last byte being written. The number of data bytes must be at least 2 to properly distinguish from the write access to set the address counter in random read accesses.

DDC Write Access

11.6 SPI Port

A Serial Peripheral Interface (SPI) bus is available with selected receivers. See our online product descriptions for availability.

SPI is a four-wire synchronous communication interface. In contrast to UART, the master provides the clock signal, which therefore doesn't need to be specified for the slave in advance. Moreover, a baud rate setting is not applicable for the slave. SPI modes 0-3 are implemented and can be configured using the field mode.spiMode in CFG-PRT for SPI (default is SPI mode 0).

The SPI clock speed is limited depending on hardware and firmware versions!

11.6.1 Maximum SPI clock speed

u-blox 8 / u-blox M8 receivers support a maximum SPI clock speed of 5.5 MHz.

11.6.2 Read Access

As the register mode is not implemented for the SPI port, only the UBX/NMEA message stream is provided. This stream is accessed using the Back-To-Back Read and Write Access (see section Back-To-Back Read and Write Access). When no data is available to be written to the receiver, MOSI should be held logic high, i.e. all bytes written to the receiver are set to 0xFF.

To prevent the receiver from being busy parsing incoming data, the parsing process is stopped after 50 subsequent bytes containing 0xFF. The parsing process is re-enabled with the first byte not equal to 0xFF. The number of bytes to wait for deactivation (50 by default) can be adjusted using the field mode.ffCnt in CFG-PRT for SPI, which is only necessary when messages shall be sent containing a large number of subsequent 0xFF bytes.

If the receiver has no more data to send, it sets MISO to logic high, i.e. all bytes transmitted decode to 0xFF. An efficient parser in the host will ignore all 0xFF bytes which are not part of a message and will resume data processing as soon as the first byte not equal to 0xFF is received.

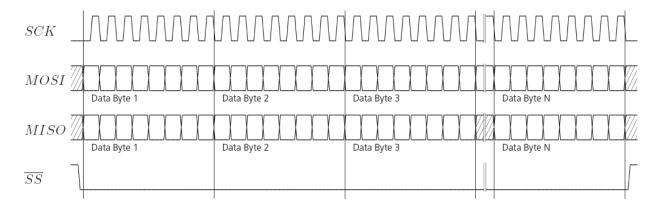

11.6.3 Back-To-Back Read and Write Access

The receiver does not provide any write access except for writing UBX and NMEA messages to the receiver, such as configuration or aiding data. For every byte written to the receiver, a byte will simultaneously be read from the receiver. While the master writes to MOSI, at the same time it

needs to read from MISO, as any pending data will be output by the receiver with this access. The data on MISO represents the results from a current address read, returning 0xFF when no more data is available.

SPI Back-To-Back Read/Write Access

11.7 How to change between protocols

Reconfiguring a port from one protocol to another is a two-step process:

- Step 1: the preferred protocol(s) needs to be enabled on a port using UBX-CFG-PRT. One port can handle several protocols at the same time (e.g. NMEA and UBX). By default, all ports are configured for UBX and NMEA protocol so in most cases, it's not necessary to change the port settings at all. Port settings can be viewed and changed using the UBX-CFG-PRT messages.
- Step 2: activate certain messages on each port using UBX-CFG-MSG.

12 Multiple GNSS assistance (MGA)

12.1 Introduction

Users would ideally like GNSS receivers to provide accurate position information the moment the receivers are turned on. With standard GNSS receivers there can be a significant delay in providing the first position fix, principally because the receiver needs to obtain data from several satellites and the satellites transmit that data slowly. Under adverse signal conditions, data downloads from the satellites to the receiver can take minutes, hours or even fail altogether.

Assisted GNSS (A-GNSS) is a common solution to this problem and involves some form of reference network of receivers that collect data such as ephemeris, almanac, accurate time and satellite status and pass this onto to the target receiver via any suitable communications link. Such assistance data enables the receiver to compute a position within a few seconds, even under poor signal conditions.

The UBX-MGA message class provides the means for delivering assistance data to u-blox receivers and customers can obtain it from the u-blox AssistNow Online or AssistNow Offline Services. Alternatively they can obtain assistance data from third-party sources (e.g. SUPL/RRLP) and generate the appropriate UBX-MGA messages to send this data to the receiver.

12.2 Assistance Data

u-blox receivers currently accept the following types of assistance data:

- **Position:** Estimated receiver position can be submitted to the receiver using the UBX-MGA-INI-POS_XYZ or UBX-MGA-INI-POS_LLH messages.
- Time: The current time can either be supplied as an inexact value via the standard communication interfaces, suffering from latency depending on the baud rate, or using hardware time synchronization where an accurate time pulse is connected to an external interrupt. The preferred option is to supply UTC time using the UBX-MGA-INI-TIME_UTC
 message, but times referenced to some GNSS can be delivered with the UBX-MGA-INI-TIME_GNSS
 message.
- Clock drift: An estimate of the clock drift can be sent to the receiver using the UBX-MGA-INI-CLKD message.
- **Frequency:** It is possible to supply hardware frequency aiding by connecting a periodic rectangular signal with a frequency up to 500 kHz and arbitrary duty cycle (low/high phase duration must not be shorter than 50 ns) to an external interrupt, and providing the applied frequency value using the UBX-MGA-INI-FREQ message.
- Current orbit data: Each different GNSS transmits orbit data in slightly different forms. For each system there are separate messages for delivering ephemeris and almanac. So for example GPS ephemeris is delivered to the receiver using the UBX-MGA-GPS-EPH message, while GLONASS almanac is delivered with the UBX-MGA-GLO-ALM message.
- **Predicted orbit data:** UBX-MGA-ANO messages can be used to supply predictions of future orbit information to a u-blox receiver. These messages can be obtained from the AssistNow Offline Service and allow a receiver to improve its TTFF even when it is no longer connected to the internet.
- Auxiliary information: Each GNSS transmits some auxiliary data (such as SV health information or UTC parameters) to the receiver. A selection of messages exist for providing such information to the receiver, such as UBX-MGA-GPS-IONO for ionospheric data from GPS.
- **EOP:** Earth Orientation Parameters can be sent to the receiver using the UBX-MGA-INI-EOP message. This will replace the default model used by the AssistNow Autonomous feature and may improve performance (particularly as the receiver gets older and the built-in model decays).
- Navigation Database: u-blox receivers can be instructed to dump the current state of their internal navigation database with the UBX-MGA-DBD-POLL message; sending this information back to the receiver (e.g. after a period when the receiver was turned off) restores the database to its former state, and thus allows the receiver to restart rapidly.

12.3 AssistNow Online

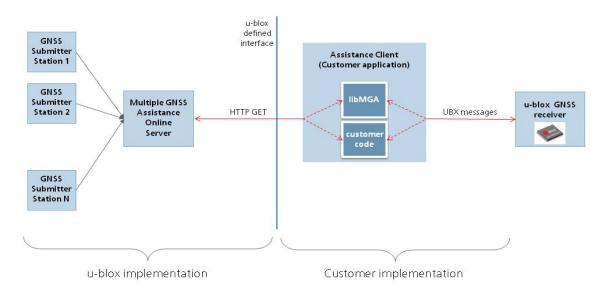

AssistNow Online is u-blox' end-to-end Assisted GNSS (A-GNSS) solution for receivers that have access to the internet. Data supplied by the AssistNow Online Service can be directly uploaded to a u-blox receiver in order to substantially reduce Time To First Fix (TTFF), even under poor signal conditions. The system works by collecting data such as ephemeris and almanac from the satellites through u-blox' Global Reference Network of receivers and providing this data to customers in a convenient form that can be forwarded on directly to u-blox receivers.

The AssistNow Online Service uses a simple, stateless, HTTP interface. Therefore, it works on all standard mobile communication networks that support internet access, including GPRS, UMTS and Wireless LAN. No special arrangements need to be made with mobile network operators to

enable AssistNow Online.

Multiple GNSS Assistance Architecture

The data returned by the AssistNow Online Service is a sequence of UBX-MGA messages, starting with an estimate of the current time in the form of a UBX-MGA-INI-TIME_UTC message.

AssistNow Online currently supports GPS, GLONASS, BeiDou, Galileo, and QZSS.

Customers may choose to use third party sources of assistance data instead of using the AssistNow Online Service. Customers choosing this option will need to ensure that the data is converted from the format used by the third party source to the appropriate MGA messages. However, it is important to ensure that the receiver has an estimate of the current time before it processes any other assistance data. For this reason, it is strongly recommended to send a UBX-MGA-INI-TIME_UTC or UBX-MGA-INI-TIME_GNSS as the first message of any assistance.

12.3.1 Host Software

As u-blox receivers have no means to connect directly with the internet, the AssistNow Online system can only work if the host system that contains the receiver can connect to the internet, download the data from the AssistNow Online Service and forward it on to the receiver. In the simplest case that may involve fetching the data from the AssistNow Online Service (by means of a single HTTP GET request), and sending the resulting data to the receiver.

Depending on the circumstances, it may be beneficial for the host software to include:

- Creating an appropriate UBX-MGA-INI-TIME_UTC message to deliver a better sense of time to the receiver, especially if the host system has a very good sense of the current time and can deliver a time pulse to one of the receiver's EXTINT pins.
- Enable and use flow control to prevent loss of data due to buffer overflow in the receiver.
- u-blox provides the source code for an example library, called libMGA, that provides all of

the functionality we expect in most host software.

12.3.2 AssistNow Online Sequence

A typical sequence of use of the AssistNow Online Service comprises the following steps:

- Power-up the u-blox receiver
- · Request data from the AssistNow Online Service
- Optionally send UBX-MGA-INI-TIME_UTC followed by hardware time synchronization pulse if hardware time synchronization is required.
- Send the UBX messages obtained from the AssistNow Online Service to the receiver.

12.3.3 Flow Control

u-blox receivers aim to process incoming messages as quickly as possible, but there will always be a small delay in processing each message. Uploading assistance data to the receiver can involve sending as many as one hundred individual messages to the receiver, one after the other. If the communication link is fast, and/or the receiver is busy (trying to acquire new signals), it is possible that the internal buffers will overflow and some messages will be lost. In order to combat this, u-blox receivers support an optional flow control mechanism for assistance.

Flow control is activated by setting the ackAiding parameter in the UBX-CFG-NAVX5 message.

As a result the receiver will issue an acknowledgement message (UBX-MGA-ACK) for each assistance message it successfully receives. The host software can examine these acknowledgements to establish whether there were any problems with the data sent to the receiver and deduce (by the lack of acknowledgement) if any messages have been lost. It may then be appropriate to resend some of the assistance messages.

The simplest way to implement flow control would be to send one UBX-MGA assistance message at a time, waiting for the acknowledgement, before sending the next. However, such a strategy is likely to introduce significant delays into the whole assistance process. The best strategy will depend on the amount of assistance data being sent and the nature of the communications link (e.g. baud rate of serial link). u-blox recommends that when customers are developing their host software they start by sending all assistance messages and then analyse the resulting acknowledgements to see whether there have been significant losses. Adding small delays during the transmission may be a simple but effective way to avoid substantial loss of data.

12.3.4 Authorization

The AssistNow Online Service is only available for use by u-blox customers. In order to use the services, customers will need to obtain an authorization token from u-blox. This token must be supplied as a parameter whenever a request is made to either service.

12.3.5 Service Parameters

The information exchange with the AssistNow Online Service is based on the HTTP protocol. Upon reception of an HTTP GET request, the server will respond with the required messages in binary format or with an error string in text format. After delivery of all data, the server will terminate the connection.

The HTTP GET request from the client to the server should contain a standard HTTP query string in the request URL. The query string consists of a set of "key=value" parameters in the following form:

key=value;key=value;

The following rules apply:

- The order of keys is not important.
- · Keys and values are case sensitive.
- Keys and values must be separated by an equals character ('=').
- Key/value pairs must be separated by semicolons (';').
- If a value contains a list, each item in the list must be separated by a comma (',').

The following table describes the keys that are supported.

AssistNow Online Parameter Keys

| Key Name | Unit/Range | Optional | Description |
|-------------|------------|-----------|--|
| token | String | Mandatory | The authorization token supplied by u-blox when a client registers to use the service. |
| gnss | String | Mandatory | A comma separated list of the GNSS for which data should be |
| | | | returned. Valid GNSS are: gps, qzss and glo. |
| datatype | String | Mandatory | A comma separated list of the data types required by the |
| | | | client. Valid data types are: eph, alm, aux and pos. Time data |
| | | | is always returned for each request. If the value of this |
| | | | parameter is an empty string, only time data will be returned. |
| lat | Numeric | Optional | Approximate user latitude in WGS 84 expressed in degrees |
| | [degrees] | | and fractional degrees. Must be in range -90 to 90. Example: |
| | | | lat=47.2. |
| lon | Numeric | Optional | Approximate user longitude in WGS 84 expressed in degrees |
| | [degrees] | | and fractional degrees. Must be in range -180 to 180. Example: |
| | | | lon=8.55. |
| alt | Numeric | Optional | Approximate user altitude above WGS 84 Ellipsoid. If this |
| | [meters] | | value is not provided, the server assumes an altitude of 0 |
| | | | meters. Must be in range -1000 to 50000. |
| pacc | Numeric | Optional | Approximate accuracy of submitted position (see position |
| | [meters] | | parameters note below). If this value is not provided, the |
| | | | server assumes an accuracy of 300 km. Must be in range 0 to |
| | | | 600000. |
| tacc | Numeric | Optional | The timing accuracy (see time parameters note below). If this |
| | [seconds] | | value is not provided, the server assumes an accuracy of 10 |
| | | | seconds. Must be in range 0 to 3600. |
| latency | Numeric | Optional | Typical latency between the time the server receives the |
| | [seconds] | | request, and the time when the assistance data arrives at the |
| | | | u-blox receiver. The server can use this value to correct the |
| | | | time being transmitted to the client. If this value is not |
| | | | provided, the server assumes a latency of 0. Must be in range |
| | | | 0 to 3600. |
| filteronpos | | Optional | If present, the ephemeris data returned to the client will only |
| | required) | | contain data for the satellites which are likely to be visible |
| | | | from the approximate position provided by the lat, lon, alt and |
| | | | pacc parameters. If the lat and lon parameters are not |
| | | | provided the service will return an error. |

AssistNow Online Parameter Keys continued

| Key Name | Unit/Range | Optional | Description |
|------------|------------|----------|--|
| filteronsv | String | Optional | A comma separated list of u-blox gnssld:svld pairs. The |
| | | | ephemeris data returned to the client will only contain data |
| | | | for the listed satellites. |

Thus, as an example, a valid parameter string would be:

token=XXXXXXXXXXXXXXXXXXXXXXXX;gnss=gps,qzss;datatype=eph,pos,aux;lat=47.28;lon=8.56; pacc=1000

12.3.5.1 Position parameters (lat, lon, alt and pacc)

The position parameters (lat, lon, alt and pacc) are used by the server for two purposes:

- If the filteronpos parameter is provided, the server determines the currently visible satellites at the user position, and only sends the ephemeris data of those satellites which should be in view at the location of the user. This reduces bandwidth requirements. In this case the 'pacc' value is taken into account, meaning that the server will return all SVs visible in the given uncertainty region.
- If the datatype 'pos' is requested, the server will return the position and accuracy in the response data. When this data is supplied to the u-blox receiver, depending on the accuracy of the provided data, the receiver can then choose to select a better startup strategy. For example, if the position is accurate to 100 km or better, the u-blox receiver will choose to go for a more optimistic startup strategy. This will result in quicker startup time. The receiver will decide which strategy to choose, depending on the 'pacc' parameter. If the submitted user position is less accurate than what is being specified with the 'pacc' parameter, then the user will experience prolonged or even failed startups.

12.3.5.2 Time parameters (tacc and latency)

Time data is always returned with each request. The time data refers to the time at which the response leaves the server, corrected by an optional latency value. This time data provided by the service is accurate to approximately 10 ms but by default the time accuracy is indicated to be +/- 10 seconds in order to account for network latency and any time between the client receiving the data and it being provided to the receiver.

If both the network latency and the client latency can safely be assumed to be very low (or are known), the client can choose to set the accuracy of the time message (tacc) to a much smaller value (e.g. 0.5 s). This will result in a faster TTFF. The latency can also be adjusted as appropriate. However, these fields should be used with caution: if the time accuracy is not correct when the time data reaches the receiver, the receiver may experience prolonged or even failed start-ups.

For optimal results, the client should establish an accurate sense of time itself (e.g. by calibrating its system clock using a local NTP service) and then modify the time data received from the service as appropriate.

12.3.6 Multiple Servers

u-blox has designed and implemented the AssistNow Online Service in a way that should provide very high reliability. Nonetheless, there will be rare occasions when a server is not available (e.g. due to failure or some form of maintenance activity). In order to protect customers against the impact of such outages, u-blox will run at least two instances of the AssistNow Online Service on independent machines. Customers will have a free choice of requesting assistance data from any

of these servers, as all will provide the same information. However, should one fail for whatever reason, it is highly unlikely that the other server(s) will also be unavailable. Therefore customers requiring the best possible availability are recommended to implement a scheme where they direct their requests to a chosen server, but, if that server fails to respond, have a fall-back mechanism to use another server instead.

12.4 AssistNow Offline

AssistNow Offline is a feature that combines special firmware in u-blox receivers and a proprietary service run by u-blox. It is targeted at receivers that only have occasional internet access and so cannot use AssistNow Online. AssistNow Offline speeds up Time To First Fix (TTFF), typically to considerably less than 10 s

AssistNow Offline currently supports GPS and GLONASS. u-blox intends to expand the AssistNow Offline Service to support other GNSS (such as BeiDou and Galileo) in due course.

The AssistNow Offline Service uses a simple, stateless, HTTP interface. Therefore, it works on all standard mobile communication networks that support internet access, including GPRS, UMTS and Wireless LAN. No special arrangements need to be made with mobile network operators to enable AssistNow Offline.

Users of AssistNow Offline are expected to download data from the AssistNow Offline Service, specifying the time period they want covered (1 to 5 weeks) and the types of GNSS. This data must be uploaded to a u-blox receiver, so that it can estimate the positions of the satellites, when no better data is available. Using these estimates will not provide as accurate a position fix as if current ephemeris data is used, but it will allow much faster TTFFs in nearly all cases.

The data obtained from the AssistNow Offline Service is organised by date, normally a day at a time. Consequently the more weeks for which coverage is requested, the larger the amount of data to handle. Similarly, each different GNSS requires its own data and in the extreme cases, several hundred kilobytes of data will be provided by the service. This amount can be reduced by requesting lower resolution, but this will have a small negative impact on both position accuracy and TTFF. See section Offline Service Parameters for details of how to specify these options.

The downloaded Offline data is encoded in a sequence of UBX-MGA-ANO messages, one for every SV for every day of the period covered. Thus, for example, data for all GPS SVs for 4 weeks will involve in excess of 900 separate messages, taking up around 70 kbytes. Where a u-blox receiver has flash storage, all the data can be directly uploaded to be stored in the flash until it is needed. In this case, the receiver will automatically select the most appropriate data to use at any time. See section flash-based AssistNow Offline for further details.

AssistNow Offline can also be used where the receiver has no flash storage, or there is insufficient spare flash memory. In this case the customer's system must store the AssistNow Offline data until the receiver needs it and then upload only the appropriate part for immediate use. See section host-based AssistNow Offline for further details.

12.4.1 Service Parameters

The information exchange with the AssistNow Offline Service is based on the HTTP protocol. Upon reception of an HTTP GET request, the server will respond with the required messages in binary format or with an error string in text format. After delivery of all data, the server will terminate the connection.

The HTTP GET request from the client to the server should contain a standard HTTP querystring

in the request URL. The querystring consists of a set of "key=value" parameters in the following form:

key=value;key=value;

The following rules apply:

- The order of keys is not important.
- · Keys and values are case sensitive.
- Keys and values must be separated by an equals character ('=').
- Key/value pairs must be separated by semicolons (';').
- If a value contains a list, each item in the list must be separated by a comma (',').

The following table describes the keys that are supported.

AssistNow Offline Parameter Keys

| Key Name | Unit/Range | Optional | Description |
|------------|------------|-----------|---|
| token | String | Mandatory | The authorization token supplied by u-blox when a client |
| | | | registers to use the service. |
| gnss | String | Mandatory | A comma separated list of the GNSS for which data should be |
| | | | returned. The currently supported GNSS are: gps and glo. |
| period | Numeric | Optional | The number of weeks into the future the data should be valid |
| | [weeks] | | for. Data can be requested for up to 5 weeks in to the future. If |
| | | | this value is not provided, the server assumes a period of 4 |
| | | | weeks. |
| resolution | Numeric | Optional | The resolution of the data: 1=every day, 2=every other day, |
| | [days] | | 3=every third day. If this value is not provided, the server |
| | | | assumes a resolution of 1 day. |

Thus, as an example, a valid parameter string would be:

token=XXXXXXXXXXXXXXXXXXXXX;gnss=gps,glo;

12.4.2 Authorization

The AssistNow Offline Service uses the same authorization process as AssistNow Online; see above for details.

12.4.3 Multiple Servers

The AssistNow Offline Service uses the same multiple server mechanism to provide high availability as AssistNow Online; see above for details.

12.4.4 Time, Position and Almanac

While AssistNow Offline can be used on its own, it is expected that the user will provide estimates of the receiver's current position, the current time and ensure that a reasonably up to date almanac is available. In most cases this information is likely to be available without the user needing to do anything. For example, where the receiver is connected to a battery backup power supply and has a functioning real time clock (RTC), the receiver will keep its own sense of time and will retain the last known position and any almanac. However, should the receiver be completely unpowered before startup, then it will greatly improve TTFF if time, position and almanac can be supplied in some form.

Almanac data has a validity period of several weeks, so it can be downloaded from the AssistNow

Online service at roughly the same time the Offline data is obtained. It can then be stored in the host for uploading on receiver startup, or it can be transferred to the receiver straight away and preserved there (provided suitable non-volatile storage is available).

Obviously, where a receiver has a functioning RTC, it should be able to keep its own sense of time, but where no RTC is fitted (or power is completely turned off), providing a time estimate via the UBX-MGA-INI-TIME_UTC message will be beneficial.

Similarly, where a receiver has effective non-volatile storage, the last known position will be recalled, but if this is not the case, then it will help TTFF to provide a position estimate via one of the <code>UBX-MGA-INI-POS_XYZ</code> or <code>UBX-MGA-INI-POS_LLH</code> messages.

Where circumstance prevent the provision of all three of these pieces of data, providing some is likely to be better than none at all.

12.4.5 Flash-based AssistNow Offline

Flash-based AssistNow Offline functionality means that AssistNow Offline data is stored in the flash memory connected to the chip.

The user's host system must download the data from the AssistNow Offline service when an internet connection is available, and then deliver all of that data to the u-blox receiver. As the total amount of data to be uploaded is large (typically around 100 kbytes) and writing to flash memory is slow, the upload must be done in blocks of up to 512 bytes, one at a time. The UBX-MGA-FLASH-DATA message is used to transmit each block to the receiver.

AssistNow Offline data stored in flash memory is not affected by any reset of the receiver. The only simple ways to clear it are to completely erase the whole flash memory or to overwrite it with a new set of AssistNow Offline data. Uploading a dummy block of data (e.g. all zeros) will also have the effect of deleting the data, although a small amount of flash storage will be used.

12.4.5.1 Flash-based Storage Procedure

The following steps are a typical sequence for transferring AssistNow Offline data into the receiver's flash memory:

- The host downloads a copy of a latest data from the AssistNow Offline service and stores it locally.
- It sends the first 512 bytes of that data using the UBX-MGA-FLASH-DATA message.
- It awaits a UBX-MGA-FLASH-ACK message in reply.
- Based on the contents of the UBX-MGA-FLASH-ACK message it, sends the next block, resends the last block or aborts the whole process.
- The above three steps are repeated until all the rest of the data has been successfully transferred (or the process has been aborted).
- The host sends an UBX-MGA-FLASH-STOP message to indicate completion of the upload.
- It awaits the final UBX-MGA-FLASH-ACK message in reply. Background processing in the receiver
 prepares the downloaded data for use at this stage. Particularly if the receiver is currently busy,
 this may take quite a few seconds, so the host has to be prepared for a delay before the UBXMGA-FLASH-ACK is seen.

Note that the final block may be smaller than 512 bytes (where the total data size is not perfectly divisible by 512). Also, the <code>UBX-MGA-FLASH-ACK</code> messages are distinct from the <code>UBX-MGA-ACK</code> messages used for other AssistNow functions.

Any existing data will be deleted as soon as the first block of new data arrives, so no useful data will be available till the completion of the data transfer. Each block of data has a sequence number, starting at zero for the first block. In order to guard against invalid partial data downloads the receiver will not accept blocks which are out of sequence.

12.4.6 Host-based AssistNow Offline

Host-based AssistNow Offline involves AssistNow Offline data being stored until it is needed by the user's host system in whatever memory it has available.

The user's host system must download the data from the AssistNow Offline service when an internet connection is available, but retain it until the time the u-blox receiver needs it. At this point, the host must upload just the relevant portion of the data to the receiver, so that the receiver can start using it. This is achieved by parsing all the data and selecting for upload to the receiver only those UBX-MGA-ANO messages with a date-stamp nearest the current time. As each is a complete UBX message it can be sent directly to the receiver with no extra packaging. If required the user can select to employ flow control, but in most cases this is likely to prove unnecessary.

When parsing the data obtained from the AssistNow Offline service the following points should be noted:

- The data is made up of a sequence of UBX-MGA-ANO messages.
- Customers should not rely on the messages all being of a fixed size, but should read their length from the UBX header to work out where the message ends (and where the next begins).
- Each message indicates the SV for which it is applicable through the svld and gnssld fields.
- Each message contains a date-stamp within the year, month and day fields.
- Midday (UTC) on the day indicated should be considered to be the point at which the data is most applicable.
- The messages will be ordered chronologically, earliest first.
- Messages with same date-stamp will be ordered by ascending gnssld and then ascending svld.

12.4.6.1 Host-based Procedure

The following steps are a typical sequence for host-based AssistNow Offline:

- The host downloads a copy of the latest data from the AssistNow Offline service and stores it locally.
- Optionally it may also download a current set of almanac data from the AssistNow Online service.
- It waits until it wants to use the u-blox receiver.
- If necessary it uploads any almanac, position estimate and/or time estimate to the receiver.
- The host scans through AssistNow Offline data looking for entries with a date-stamp that most closely matches the current (UTC) time/date.
- The host sends each such UBX-MGA-ANO message to the receiver.

Note that when data has been downloaded from the AssistNow Offline service with the (default) resolution of one day, the means for selecting the closest matching date-stamp is simply to look for ones with the current (UTC) date.

12.5 Preserving Information During Power-off

The performance of u-blox receivers immediately after they are turned on is enhanced by providing them with as much useful information as possible. Assistance (both Online and Offline) is one way to achieve this, but retaining information from previous use of the receiver can be just as valuable. All the types of data delivered by assistance can be retained while the receiver is powered down for use when power is restored. Obviously the value of this data will diminish as time passes, but in many cases it remains very useful and can significantly improve time to first fix.

The are several ways in which a u-blox receiver can retain useful data while it is powered down, including:

- **Battery Backed RAM:** The receiver can be supplied with sufficient power to maintain a small portion of internal storage, while it is otherwise turned off. This is the best mechanism, provided that the small amount of electrical power required can be supplied continuously.
- Save on Shutdown: The receiver can be instructed to dump its current state to the attached flash memory (where fitted) as part of the shutdown procedure; this data is then automatically retrieved when the receiver is restarted. See the description of the UBX-UPD-SOS messages for more information.
- **Database Dump:** The receiver can be asked to dump the state of its internal database in the form of a sequence of UBX messages reported to the host; these messages can be stored by the host and then sent back to the receiver when it has been restarted. See the description of the UBX-MGA-DBD messages for more information.

12.6 AssistNow Autonomous

(Note: some functionality described in this chapter may not be available in protocol versions less than 18).

12.6.1 Introduction

The assistance scenarios covered by AssistNow Online and AssistNow Offline require an online connection and a host that can use this connection to download aiding data and provide this to the receiver when required.

The AssistNow Autonomous feature provides a functionality similar to AssistNow Offline without the need for a host and a connection. Based on a broadcast ephemeris downloaded from the satellite (or obtained by AssistNow Online) the receiver can autonomously (i.e. without any host interaction or online connection) generate an accurate satellite orbit representation («AssistNow Autonomous data») that is usable for navigation much longer than the underlying broadcast ephemeris was intended for. This makes downloading new ephemeris or aiding data for the first fix unnecessary for subsequent start-ups of the receiver.

The AssistNow Autonomous feature is disabled by default. It can be enabled using the UBX-CFG-NAVX5 message.

12.6.2 Concept

The figure below illustrates the AssistNow Autonomous concept in a graphical way. Note that the figure is a qualitative illustration and is not to scale.

 A broadcast ephemeris downloaded from the satellite is a precise representation of a part (for GPS nominally four hours) of the satellite's true orbit (trajectory). It is not usable for positioning

beyond this validity period because it diverges dramatically from the true orbit afterwards.

- The AssistNow Autonomous orbit is an extension of one or more broadcast ephemerides. It
 provides a long-term orbit for the satellite for several revolutions. Although this orbit is not
 perfectly precise it is a sufficiently accurate representation of the true orbit to be used for
 navigation.
- The AssistNow Autonomous data is automatically and autonomously generated from downloaded (or assisted) ephemerides. The data is stored automatically in the on-chip batterybacked memory (BBR). Optionally, the data can be backed-up in external flash memory or on the host. The number of satellites for which data can be stored depends on the receiver configuration and may change during operation.
- If no broadcast ephemeris is available for navigation AssistNow Autonomous automatically generates the required parts of the orbits suitable for navigation from the stored data. The data is also automatically kept current in order to minimize the calculation time once the navigation engine needs orbits.
- The operation of the AssistNow Autonomous feature is transparent to the user and the operation of the receiver. All calculations are done in background and do not affect the normal operation of the receiver.
- The AssistNow Autonomous subsystem automatically invalidates data that has become too old and that would introduce unacceptable positioning errors. This threshold is configurable (see below).
- The prediction quality will be automatically improved if the satellite has been observed multiple times. However, this requires the availability of a suitable flash memory (see the integration manual for a list of supported devices). Improved prediction quality also positively affects the maximum usability period of the data.
- AssistNow Autonomous considers GPS, GLONASS, Galileo and BeiDou satellites only. It will not
 consider satellites on orbits with an eccentricity of >0.05 (e.g., Galileo E18). For GLONASS
 support a suitable flash memory is mandatory because a single broadcast ephemeris spans to
 little of the orbit (only approx. 30 minutes) in order to extend it in a usable way. Only multiple
 observations of the same GLONASS satellite that span at least four hours will be used to
 generate data.

12.6.3 Interface

Several UBX protocol messages provide interfaces to the AssistNow Autonomous feature. They are:

- The UBX-CFG-NAVX5 message is used to enable or disable the AssistNow Autonomous feature. It is disabled by default. Once enabled, the receiver will automatically produce AssistNow Autonomous data for newly received broadcast ephemerides and, if that data is available, automatically provide the navigation subsystem with orbits when necessary and adequate. The message also allows for a configuration of the maximum acceptable orbit error. See the next section for an explanation of this feature. It is recommended to use the firmware default value that corresponds to a default orbit data validity of approximately three days (for GPS satellites observed once) and up to six days (for GPS and GLONASS satellites observed multiple times over a period of at least half a day).
- Note that disabling the AssistNow Autonomous feature will delete all previously collected satellite observation data from the flash memory.
- The UBX-NAV-AOPSTATUS message provides information on the current state of the AssistNow Autonomous subsystem. The status indicates whether the AssistNow Autonomous subsystem is currently idle (or not enabled) or busy generating data or orbits. Hosts should monitor this information and only power-off the receiver when the subsystem is idle (that is, when the status field shows a steady zero).
- The UBX-NAV-SAT message indicates the use of AssistNow Autonomous orbits for individual satellites.

- The UBX-NAV-ORB message indicates the availability of AssistNow Autonomous orbits for individual satellites.
- The UBX-MGA-DBD message provides a means to retrieve the AssistNow Autonomous data from the receiver in order to preserve the data in power-off mode where no battery backup is available. Note that the receiver requires the absolute time (i.e. full date and time) to calculate AssistNow Autonomous orbits. For best performance it is, therefore, recommended to supply this information to the receiver using the UBX-MGA-INI-TIME_UTC message in this scenario.
- The Save-on-Shutdown feature preserves AssistNow Autonomous data.

12.6.4 Benefits and Drawbacks

AssistNow Autonomous can provide quicker start-up times (lower the TTFF) provided that data is available for enough visible satellites. This is particularly true under weak signal conditions where it might not be possible to download broadcast ephemerides at all, and, therefore, no fix at all would be possible without AssistNow Autonomous (or A-GNSS). It is, however, required that the receiver roughly knows the absolute time, either from an RTC or from time-aiding (see the Interface section above), and that it knows which satellites are visible, either from the almanac or from tracking the respective signals.

The AssistNow Autonomous orbit (satellite position) accuracy depends on various factors, such as the particular type of satellite, the accuracy of the underlying broadcast ephemeris, or the orbital phase of the satellite and Earth, and the age of the data (errors add up over time).

AssistNow Autonomous will typically extend a broadcast ephemeris for up to three to six days. The UBX-CFG-NAVX5 (see above) message allows changing this threshold by setting the «maximum acceptable modelled orbit error» (in meters). Note that this number does not reflect the true orbit error introduced by extending the ephemeris. It is a statistical value that represents a certain expected upper limit based on a number of parameters. A rough approximation that relates the maximum extension time to this setting is: maxError[m] = maxAge[d] * f, where the factor f is 30 for data derived from satellites seen once and and 16 for data derived for satellites seen multiple times during a long enough time period (see the Concept section above).

There is no direct relation between (true and statistical) orbit accuracy and positioning accuracy. The positioning accuracy depends on various factors, such as the satellite position accuracy, the number of visible satellites, and the geometry (DOP) of the visible satellites. Position fixes that include AssistNow Autonomous orbit information may be significantly worse than fixes using only broadcast ephemerides. It might be necessary to adjust the limits of the Navigation Output Filters.

A fundamental deficiency of any system to predict satellite orbits precisely is unknown future events. Hence, the receiver will not be able to know about satellites that will have become unhealthy, have undergone a clock swap, or have had a manoeuvre. This means that the navigation engine might rarely mistake a wrong satellite position as the true satellite position. However, provided that there are enough other good satellites, the navigation algorithms will eventually eliminate a defective orbit from the navigation solution.

The repeatability of the satellite constellation is a potential pitfall for the use of the AssistNow Autonomous feature. For a given location on Earth the (GPS) constellation (geometry of visible satellites) repeats every 24 hours. Hence, when the receiver «learned» about a number of satellites at some point in time the same satellites will in most places not be visible 12 hours later, and the available AssistNow Autonomous data will not be of any help. Again 12 hours later, however, usable data would be available because it had been generated 24 hours ago.

The longer a receiver observes the sky the more satellites it will have seen. At the equator, and with full sky view, approximately ten (GPS) satellites will show up in a one hour window. After four hours of observation approx. 16 satellites (i.e. half the constellation), after 10 hours approx. 24 satellites (2/3rd of the constellation), and after approx. 16 hours the full constellation will have been observed (and AssistNow Autonomous data generated for). Lower sky visibility reduces these figures. Further away from the equator the numbers improve because the satellites can be seen twice a day. E.g. at 47 degrees north the full constellation can be observed in approx. 12 hours with full sky view.

The calculations required for AssistNow Autonomous are carried out on the receiver. This requires energy and users may therefore occasionally see increased power consumption during short periods (several seconds, rarely more than 60 seconds) when such calculations are running. Ongoing calculations will automatically prevent the power save mode from entering the power-off state. The power-down will be delayed until all calculations are done.

The AssistNow Offline and AssistNow Autonomous features are exclusive and should not be used at the same time. Every satellite will be ignored by AssistNow Autonomous if there is AssistNow Offline data available for it.

13 Power Management

u-blox receivers support different power modes. These modes represent strategies of how to control the acquisition and tracking engines in order to achieve either the best possible performance or good performance with reduced power consumption.

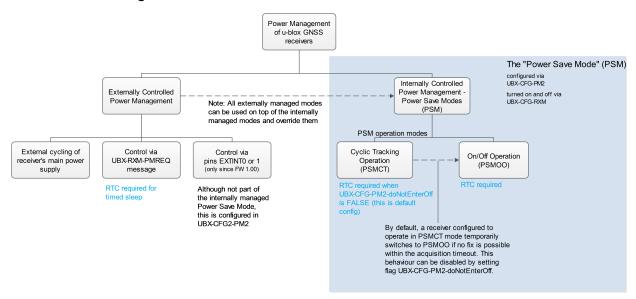

Receiver power management can split into two categories:

- Externally Controlled Power Management: This includes various modes of power management that are directly operated by the user or host device. These modes are: 1. External cycling of the receiver main power supply. 2. Instruct the receiver to turn On/Off via the UBX-RXM-PMREQ message. 3. Instruct the receiver to turn On/Off via external pins (EXTINTO or EXTINT1).
- Internally Controlled Power Management: Here the receiver makes the decision when to power down/up some/all of its internal components according to predefined parameters. It is also referred to as Power Save Modes (PSM). In PSM one of three modes of operations can be selected (not all are supported in a single firmware): 1. ON/OFF Operation (PSMOO) 2. Cyclic Tracking (PSMCT) 3. Super-Efficient Mode (Super-E).

The following figure illustrates u-blox power management modes.

u-blox Power Management

The majority of the Power Management section is detailing the Power Save Mode (Internally Controlled Power Management). However, some the concepts relevant to the Externally Controlled Power Management are detailed, such as the EXTINT Control, Wake up and Power On/Off Command.

Externally controlled power management operations can be used on top of the Internally Controlled Power Management and they do override their operation.

13.1 Continuous Mode

u-blox receivers make use of dedicated signal processing engines optimized for signal acquisition and tracking. The acquisition engine delivers rapid signal searches during cold starts or when insufficient signals are available for navigation. The tracking engine delivers signal measurements for navigation and acquires new signals as they become available during navigation. The resources of both engines are deployed adaptively to minimize overall power consumption.

13.2 Power Save Mode

Power Save Mode (PSM) allows a reduction in system power consumption by selectively switching parts of the receiver on and off. It is selected using the message UBX-CFG-RXM and configured using UBX-CFG-PM2. It is recommended to use UBX-CFG-PMS instead if available (only supported in protocol versions 18+) as it provides a simplified interface; see section Power mode setup for details.

PSM is designed to only support the operation of GPS, GLONASS, BeiDou, Galileo and QZSS. Enabling SBAS or IMES is possible only if at least one of the other systems is enabled. The PSM state machine behavior will not be altered by enabling SBAS or IMES and it will not take them into account in operation. Therefore, it is recommended to disable them (i.e., SBAS or IMES) when operating in Power Save Mode. They can be disabled using UBX-CFG-GNSS.

The logic within Power Save Mode is designed so that **Time Pulse** operation is not compromised. This means that entering all power saving states is delayed until the conditions necessary to produce a Time Pulse have been met. Therefore, in order to obtain good Power Save Mode operation, it is essential that any Time Pulse is correctly

configured with an appropriate time base, or that Time Pulses are turned off if not needed (by clearing the active flag in UBX-CFG-TP5).

For protocol versions less than 18: Power Save Mode can only be selected with GPS signals. Other GNSS are not supported.

Note: Power Save Mode is not supported in conjunction with the ADR, UDR and FTS products.

13.2.1 Operation

Power Save Mode has two modes of operation:

- Power Save Mode Cyclic Tracking (PSMCT) Operation is used when position fixes are required in short periods of 1 to 10s. In receivers that support Super-E Mode, Super-E replaces Cyclic Tracking.
- Power Save Mode ON/OFF (PSMOO) Operation is used for periods longer than 10s, and can be in the order of minutes, hours or days. (Not supported in protocol versions 23 to 23.01)

The mode of operation can be configured, and depending on the setting, the receiver demonstrates different behavior: In ON/OFF operation the receiver switches between phases of start-up/navigation and phases with low or almost no system activity (backup/sleep). In cyclic tracking the receiver does not shut down completely between fixes, but uses low power tracking instead.

Currently PSMCT is restricted to update period between 1 and 10 seconds and PSMOO is restricted to update period over 10 seconds. However, this may change in future firmware releases.

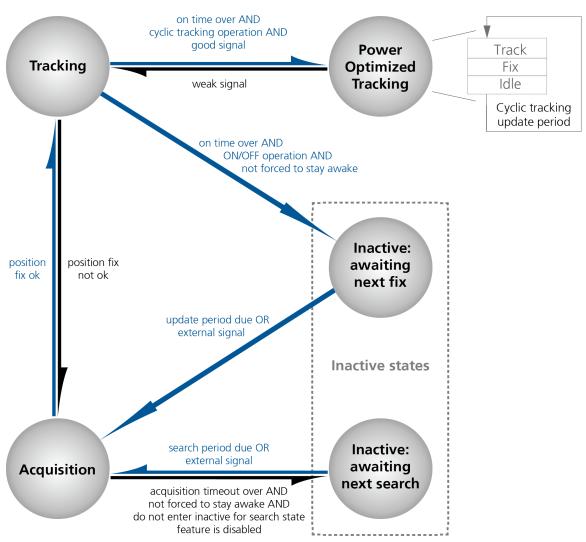

PSM is based on a state machine with five different states: (Inactive) Awaiting Next Fix and (Inactive) Awaiting Next Search states, Acquisition state, Tracking state and Power Optimized Tracking (POT) state.

- Inactive states: Most parts of the receiver are switched off.
- Acquisition state: The receiver actively searches for and acquires signals. Maximum power consumption.
- Tracking state: The receiver continuously tracks and downloads data. Less power consumption than in Acquisition state.
- POT state: The receiver repeatedly loops through a sequence of tracking (Track), calculating the position fix (Fix), and entering an idle period (Idle). No new signals are acquired and no data is downloaded. Much less power consumption than in Tracking state.

The following figure illustrates the PSM state machine:

State machine

13.2.1.1 Acquisition Timeout Logic

The receiver has internal, external and user-configurable mechanisms that determine the time to be spent in acquisition state. This logic is put in place to ensure good performance and low power consumption in different environments and scenarios. This collective logic is referred to as Acquisition Timeout.

Internal mechanisms:

- If the receiver is able to acquire weak signals but not of the quality needed to get a fix, it will transition to (Inactive) Awaiting Next Search state after the timeout configured in maxStartupStateDur or earlier if too few signals are acquired.
- If the receiver is unable to acquire any signals or it acquires a small number of extremely bad signals (e.g., no sky view), it will transition to (Inactive) Awaiting Next search state after 15 seconds or the timeout configured in maxStartupStateDur if shorter.

User-configurable mechanisms:

- minAcqTime is the minimum time that the receiver will spend in Acquisition state (see minAcqTime for details.)
- maxStartupStateDur is the maximum time that the receiver will spend in Acquisition state (see

maxStartupStateDur for details).

• doNotEnterOff forces the receiver to stay awake and in Acquisition state even when a fix is not possible (see doNotEnterOff for details).

External mechanisms:

The receiver will be forced to stay awake if extintWake is enabled and the configured EXTINT pin
is set to "high" and it will be forced to stay in (Inactive) Awaiting Next Search/Fix states if
extintBackup is enabled and the configured EXTINT pin is set to "low" (see EXTINT pin control
for details).

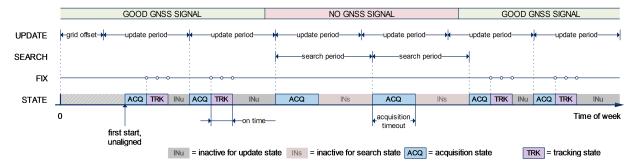

13.2.1.2 ON/OFF operation - long update period

(Not supported in protocol versions 23 to 23.01).

When the receiver is switched on, it first enters Acquisition state. If it is able to obtain a valid position fix within the time given by the Acquisition Timeout, it switches to Tracking state. Otherwise it enters (Inactive) Awaiting Next Search state and re-starts after the configured search period (minus a start-up margin). As soon as the receiver gets a valid position fix (one passing the navigation output filters), it enters Tracking state. Upon entering Tracking state, the onTime starts. Once the onTime is over, (Inactive) Awaiting Next Fix state is entered and the receiver re-starts according to the configured update grid (see section Grid offset for an explanation). If the signal is lost while in Tracking state, Acquisition state is entered. If the signal is not found within the acquisition timeout, the receiver enters (Inactive) Awaiting Next Search state. Otherwise the receiver will re-enter Tracking state and stay there until the newly started onTime is over.

The diagram below illustrates how ON/OFF operation works:

Diagram of ON/OFF operation

13.2.1.3 Cyclic tracking operation - short update period

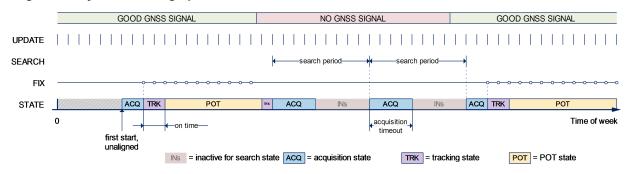

When the receiver is switched on, it first enters Acquisition state. If it is able to obtain a position fix within the time given by the acquisition timeout, it switches to Tracking state. Otherwise, it will enter (Inactive) Awaiting Next Search state and re-start within the configured search grid. After a valid position fix, Tracking state is entered and the onTime starts. In other words the onTime starts with the first valid position fix. Once the onTime is over, POT state is entered. In POT state the receiver continues to output position fixes according to the updatePeriod. To have maximum power savings, set the onTime to zero. This causes the receiver to enter POT state as soon as possible. If the signal becomes weak or is lost during POT state, Tracking state is entered. Once the signal is good again and the newly started onTime is over, the receiver will re-enter POT state. If the receiver can't get a position fix in the Tracking state, it enters Acquisition state. Should the acquisition fail as well, (Inactive) Awaiting Next Search state is entered. If doNotEnterOff is

enabled and no fix is possible, the receiver will remain in Acquisition state until a fix is possible and it will never enter (Inactive) Awaiting Next Search state.

The diagram below illustrates how cyclic tracking operation works:

Diagram of cyclic tracking operation

13.2.1.4 Super-Efficient Mode

(Not supported in protocol versions less than 23).

Super-Efficient (Super-E) Mode is a power efficient mode of operation that replaces and improves on cyclic tracking Power Save Mode (PSMCT). It uses improved clocking techiques to reduce power consumption and more sophisticated decision making for switching between "Acquisition", "Tracking" and "Power Optimized Tracking" states. This mode was developed and optimized to provide a good compromise between power efficiency and positioning accuracy in wearable applications.

13.2.1.5 User controlled operation - update and search period of zero

Setting the updatePeriod to zero causes the receiver to wait in the (Inactive) Awaiting Next Fix state until woken up by the user. Setting the search period to zero causes the receiver to wait in the (Inactive) Awaiting Next Search state indefinitely after an unsuccessful start-up. Any wake-up event will re-start the receiver. See section Wake up for more information on wake-up events.

External wake-up is required when setting update or search period to zero.

13.2.1.6 Satellite data download

The receiver is not able to download satellite data (e.g. the ephemeris) while it is working in ON/OFF or cyclic tracking operation. Therefore it has to temporarily switch to continuous operation for the time the satellites transmit the desired data. To save power the receiver schedules the downloads according to an internal timetable and only switches to continuous operation while data of interest is being transmitted by the satellites.

Each SV transmits its own ephemeris data. Ephemeris data download is feasible when the corresponding satellite has been tracked with a sufficient C/No over a certain period of time. The download is scheduled in a 30 minute grid or immediately when fewer than a certain number of visible satellites have valid ephemeris data.

Almanac, ionosphere, UTC correction and SV health data are transmitted by all SVs simultaneously. Therefore these parameters can be downloaded when a single SV is tracked with a high enough C/No.

Allowing more ephemerides to be downloaded before going into POT or (Inactive) Awaiting Next Fix state can help improve the quality of the fixes and reduce the number of wake ups needed to

download ephemerides at the cost of extra time in Acquisition state (only when an inadequate number of ephemerides are downloaded from tracked satellites).

13.2.2 Configuration

Power Save Mode is enabled and disabled with the UBX-CFG-RXM message and configured with the UBX-CFG-PM2 message.

🦙 When enabling Power Save Mode, the receiver will be unable to download or process any SBAS or IMES data. Therefore, there is no benefit in enabling them and it is recommended to disable both systems. SBAS support and IMES support can be disabled using UBX-CFG-GNSS.

A number of parameters can be used to customize PSM to any specific needs. These parameters are listed in the following table:

Power Save Mode configuration options on UBX-CFG-PM2

| Parameter | Description |
|--------------------|---|
| mode | Receiver mode of operation |
| updatePeriod | Time between two position fix attempts |
| searchPeriod | Time between two acquisition attempts if the receiver is unable to get a |
| | position fix |
| minAcqTime | Minimum time the receiver spends in Acquisition state |
| onTime | Time the receiver remains in Tracking state and produces position fixes |
| waitTimeFix | Wait for time fix before entering Tracking state |
| doNotEnterOff | Receiver does not enter (Inactive) Awaiting Next Search state if it can't get |
| | a position fix but keeps indefinitely attempting a position fix instead |
| updateRTC | Enables periodic Real Time Clock (RTC) update |
| updateEPH | Enables periodic ephemeris update |
| extintSelect | Selects EXTINT pin used with pin control feature |
| extintWake | Enables force-ON pin control feature |
| extintBackup | Enables force-OFF pin control feature |
| gridOffset | Time offset of update grid with respect to start of week |
| maxStartupStateDur | Maximum time in Acquisition state |
| optTarget | The PSM settings will be weighed towards a specific target (only |
| | supported in protocol versions 23 to 23.01) |

13.2.2.1 Mode of operation (mode)

The mode of operation to use mainly depends on the update period: For short update periods (in the range of a few seconds), cyclic tracking should be configured. For long update periods (in the range of minutes or longer), only use ON/OFF operation.

See section ON/OFF operation - long update period and Cyclic tracking operation - short update period for more information on the two modes of operation.

13.2.2.2 Reference Time Standard

In older versions (in protocol versions less than 18), only GPS can be configured for PSM, therefore, GPS time standard is used for the operation of PSM. Whereas, in newer versions where multiple GNSS can operate simultaneously (in protocol versions 18+), UTC time standard is used.

13.2.2.3 Update period (updatePeriod) and search period (searchPeriod)

The update period specifies the time between successive position fixes. If no position fix can be obtained within the acquisition timeout, the receiver will retry after the time specified by the search period. Update and search periods are fixed with respect to an absolute time grid based on reference time standard (i.e., GPS Time or UTC. see Reference Time Standard). They do not refer to the time of the last valid position fix or last position fix attempt.

New settings are ignored if the update period or the search period exceeds the maximum number of milliseconds in a week. In that case the previously stored values remain effective.

13.2.2.4 Minimum Acquisition Time (minAcqTime)

The receiver tries to obtain a position fix for at least the time given in minAcqTime. If the receiver determines that it needs more time for the given starting conditions then it will automatically prolong this time. If minAcqTime is set to zero then the minimum acquisition time is exclusively determined by the receiver. Once the minAcqTime has expired, the receiver will terminate the acquisition state if either a fix is achieved or if the receiver estimates that any signals received are insufficient (too weak or too few) for a fix to be possible.

13.2.2.5 On time (onTime)

The onTime parameter specifies how long the receiver stays in Tracking state before switching to the POT state (in PSMCT) or (Inactive) Awaiting Next Fix state (in PSMCO).

13.2.2.6 Wait for time fix (waitTimeFix)

A time fix is a fix type in which the receiver will ensure that the time is accurate and confirmed to within the limits set in UBX-CFG-NAV5. Enabling the waitTimeFix option will force the receiver to stay in Acquisition state until the time is known to within the configured limits then it will transition to Tracking state. Enabling waitTimeFix will delay the transition from Acquisition state to Tracking state by at least two extra seconds, thus, this should be taken into account (see Acquisition Timeout). It is necessary to enable waitTimeFix in timing products.

The quality of the position fixes can also be configured by setting the limits in the message UBX-CFG-NAV5. Setting harder limits in UBX-CFG-NAV5 will typically prolong the time in Acquisition state. Thus, ensuring sufficient time is given to the receiver at start-up (when externally controlled) is necessary (see Acquisition Timeout Logic). When internally controlled, the receiver can make good judgement on the time needed in Acquisition state and no further adjustments will be needed.

13.2.2.7 Maximum Startup State Duration (maxStartupStateDur)

(Only supported in protocol versions 17+).

The maxStartupStateDur is the maximum time that the receiver will spend in Startup state (i.e., Acquisition state). If the receiver is unable to acquire a valid position fix within this maximum time, it will transition to (Inactive) Awaiting Next Search state (if doNotEnterOff is disabled). Subsequently, the receiver will attempt to acquire another position fix according to the search period (see Update period (updatePeriod) and search period (searchPeriod)). If maxStartupStateDur is set to zero, the receiver will autonomously determine the maximum time to spend in Acquisition state. Note that shorter settings (below about 45s) will degrade an unaided receiver's ability to collect new Ephemeris data at low signal levels (see section Satellite

data download).

13.2.2.8 Do not enter '(Inactive) Awaiting Next Search' state when no fix (doNotEnterOff)

If this option is enabled, the receiver acts differently in case it cannot get a fix: instead of entering (Inactive) Awaiting Next Search state, it keeps attempting to acquire a position fix. In other words, the receiver will never be in (Inactive) Awaiting Next Search state and therefore searchPeriod and minAcqTime will be ignored.

13.2.2.9 Update RTC (updateRTC) and Ephemeris (updateEPH)

To maintain the ability of a fast start-up, the receiver needs to calibrate its RTC and update its ephemeris data on a regular basis. This can be ensured by activating the update RTC and update Ephemeris option. The RTC is calibrated every 5 minutes and the ephemeris data is updated approximately every 30 minutes. See section Satellite data download for more information.

13.2.2.10 EXTINT pin control

The operation of PSM can be externally controlled using either EXTINTO or EXTINT1 pin. This external control allows the user to decide when to wake up the receiver to obtain a fix and when to force the receiver into sleep/backup mode to save power. Operating the receiver externally through the EXTINT pins will override internal functions that coincide with that specific operation.

The choice of which pin to use can be configured through the extintSelect feature in UBX-CFG-PM2. Only one pin can be selected at a time but it is sufficient to perform all the required tasks.

If the Force-ON (extintWake) feature in UBX-CFG-PM2 is enabled, the receiver will not enter Inactive states for as long as the configured EXTINT pin (EXTINTO or EXTINT1) is at 'high' level. The receiver will therefore always be in Acquisition/Tracking state in PSMOO or in Acquisition/Tracking/POT state in PSMCT. When the pin level changes to 'low' the receiver will continue with its configured behavior.

If the Force-OFF (extintBackup) feature in UBX-CFG-PM2 is enabled, the receiver will enter Inactive states for as long as the configured EXTINT pin is set to 'low' until the next wake up event. Any wake-up event can wake up the receiver even while the EXTINT pin is set to 'low' (see Wake up). However, if the pin stays at 'low' state, the receiver will only wake up for the time needed to read the configuration pin settings then it will enter the Inactive state again.

If both Force-ON and Force-OFF features are enabled at the same time, the receiver PSM operation will be completely in user control. Setting 'high' on the configured EXTINT pin will wake up the receiver to get a position fix and setting 'low' will put the receiver into sleep/backup mode.

13.2.2.11 Grid offset (gridOffset)

Once the receiver has a valid time, the update grid is aligned to the start of the week of the reference time standard (midnight between Saturday and Sunday). Before having a valid time, the update grid is unaligned. A grid offset shifts the update grid with respect to the start of the week of the reference time standard. An example of usage can be found in section Use grid offset.

The grid offset is not used in cyclic tracking operation.

13.2.2.12 Optimization target

In cyclic tracking operation, the behavior of the receiver can be tuned even more closely to the application's need by choosing an appropriate optimization target.

In protocol version 23.01 two optimization targets are available:

- Performance: The receiver achieves a good GNSS performance while keeping the power consumption low.
- Power save: The receiver might sacrifice GNSS performance in favor of a reduced power consumption.

13.2.3 Features

13.2.3.1 Communication

When PSM is enabled, communication with the receiver (e.g. UBX message to disable PSM) requires particular attention. This is because the receiver may be in Inactive state and therefore unable to receive any message through its interfaces. To ensure that the configuration messages are processed by the receiver, even while in Inactive state, the following steps need to be taken:

- Send a dummy sequence of 0xFF (one byte is sufficient) to the receiver's UART interface. This will wake up the receiver if it is in Inactive state. If the receiver is not in Inactive state, the sequence will be ignored.
- Send the configuration message about half a second after the dummy sequence. If the interval between the dummy sequence and the configuration message is too short, the receiver may not yet be ready. If the interval is too long, the receiver may return to Inactive state before the configuration message was received. It is therefore important to check for a UBX-ACK-ACK reply from the receiver to confirm that the configuration message was received.
- Send the configuration save message immediately after the configuration message.

Similarly, when configuring the receiver for PSMOO (and PSMCT when doNotEnterOff is disabled), ensure that the configurations are saved. If they are not saved the receiver will enter backup mode and when it wakes up again, it would have lost the configurations and even forgets it was in power save mode. This can be avoided by using the UBX-CFG-CFG message (see Receiver Configuration for details). When operating PSM from u-center and setting the receiver to Power Save Mode in UBX-CFG-RXM, check the save configuration box. u-center will then send a UBX-CFG-CFG message after the UBX-CFG-RXM to save the configurations.

13.2.3.2 Wake up

The receiver can be woken up by generating an edge on one of the following pins:

- rising or falling edge on one of the EXTINT pins
- · rising or falling edge on the RXD1 pin
- rising or falling edge on the SPI CS pin
- rising edge on NRESET pin

All wake-up signals are interpreted as a position request, where the receiver wakes up and tries to obtain a position fix. Wake-up signals have no effect if the receiver is already in Acquisition, Tracking or POT state.

13.2.3.3 Behavior while USB host connected

As long as the receiver is connected to a USB host, it will not enter the lowest possible power state. This is because it must retain a small level of CPU activity to avoid breaching requirements of the USB specification. The drawback, however, is that power consumption is higher.

Wake up by pin/UART is possible even if the receiver is connected to a USB host. In this case the state of the pin must be changed for a duration longer than one millisecond.

13.2.3.4 Cooperation with the AssistNow Autonomous feature

If both PSM and AssistNow Autonomous features are enabled, the receiver will not enter (Inactive) Awaiting Next Fix state as long as AssistNow Autonomous carries out calculations. This prevents losing data from unfinished calculations and, in the end, reduces the total extra power needed for AssistNow Autonomous. The delay before entering (Inactive) Awaiting Next Fix state, if any, will be in the range of several seconds, rarely more than 20 seconds.

Only entering (Inactive) Awaiting Next Fix state is affected by AssistNow Autonomous. In other words: in cyclic tracking operation, AssistNow Autonomous will not interfere with the PSM (apart from the increased power consumption).

Enabling the AssistNow Autonomous feature will lead to increased power consumption while prediction is calculated. The main goal of PSM is to reduce the overall power consumption. Therefore for each application special care must be taken to judge whether AssistNow Autonomous is beneficial to the overall power consumption or not.

13.2.4 Examples

13.2.4.1 Use Grid Offset

Scenario: Get a position fix once a day at a fixed time. If the position fix cannot be obtained try again every two hours.

Solution: First set the update period to 24x3600s and the search period to 2x3600s. Now a position fix is obtained every 24 hours and if the position fix fails retrials are scheduled in two hour intervals. As the update grid is aligned to midnight Saturday/Sunday reference time standard, the position fixes happen at midnight reference time standard. By setting the grid offset to 12x3600s the position fixes are shifted to once a day at noon reference time standard. If the position fix at noon fails, retrials take place every two hours, the first at 14:00 reference time standard. Upon successfully acquiring a position fix the next fix attempt is scheduled for noon the following day.

13.2.4.2 User controlled position fix

Scenario: Get a position fix on request.

Solution: Set updatePeriod and searchPeriod to zero. Set extintSelect to the desired EXTINT pin to be used. Enable the extintWake and extintBackup features.

13.2.4.3 Use update periods of 30 minutes

Scenario: Get a position fix once every 30 minutes and acquire a fix needed for timing products.

Solution: Set mode of operation to PSMOO. Set updatePeriod to 1800 seconds. Set the search period to 120 seconds. Enable waitTimeFix feature.

13.3 Peak current settings

The peak current during acquisition can be reduced by activating the corresponding option in UBX-CFG-PM2. A peak current reduction will result in longer start-up times of the receiver.

This setting is independent of the activated mode (Continuous or Power Save Mode).

13.4 Power On/Off command

With message UBX-RXM-PMREQ the receiver can be forced to enter Inactive state (in Continuous and Power Save Mode). It will stay in Inactive state for the time specified in the message or until it is woken up by an EXTINT or activity on the RXD1, SPI CS, or NRESET pin.

Sending the message UBX-RXM-PMREQ while the receiver is in Power Save Mode will overrule PSM and force the receiver to enter Inactive state. It will stay in Inactive state until woken up. After wake-up the receiver continues working in Power Save Mode as configured.

13.5 EXTINT pin control when Power Save Mode is not active

The receiver can be forced OFF also when the Power Save Mode is not active. This works the same way as EXTINT pin control in Power Save Mode. Just as in Power Save Mode, this feature has to be enabled and configured using UBX-CFG-PM2

13.6 Measurement and navigation rate with Power Save Mode

In Continuous Mode, measurement and navigation rate is configured using UBX-CFG-RATE. In Power Save Mode however, measurement and navigation rate can differ from the configured rates as follows:

- Cyclic Operation: When in state Power Optimized Tracking, the measurement and navigation rate is determined by the updatePeriod configured in UBX-CFG-PM2. The receiver can however switch to Tracking state (e.g. to download data). When in Tracking state, the measurement and navigation rate is as configured with UBX-CFG-RATE. Note: When the receiver is no longer able to produce position fixes, it can switch from Cyclic Operation to ON/OFF Operation (if this is not disabled with the doNotEnterOff switch in UBX-CFG-PM2). In that case the remarks below are relevant.
- ON/OFF Operation: (in protocol versions less than 18) when in state Acquisition, the measurement and navigation rate is fixed to 2 Hz. All NMEA (and UBX) messages that are output upon a navigation fix are also output with a rate of 2 Hz. This must be considered when choosing the baud rate of a receiver that uses Power Save Mode! Note that a receiver might stay in Acquisition state for quite some time (can be tens of seconds under weak signal conditions). When the receiver eventually switches to Tracking state, the measurement and navigation rate will be as configured with UBX-CFG-RATE. However, (in protocol versions 18+) the measurement and navigation rate will be as configured with UBX-CFG-RATE in all active states.

13.7 Power mode setup

(Not supported in protocol versions less than 18).

In order to simplify the power saving configuration of the receiver in typical circumstances, a set of predefined setups can be selected using the message <code>UBX-CFG-PMS</code>.

Selecting one of the available setups (listed below) is the equivalent of using a combination of the configuration messages with appropriate parameters that impact the power consumption of the receiver.

Valid power mode setup in UBX-CFG-PMS

| Setup Name | Description |
|-----------------|---|
| Full Power | No compromises on power saves |
| Balanced | Power savings without performance degradation |
| Aggressive 1 Hz | Best power saving setup (1 Hz rate). This corresponds to Super-E mode |
| | performance setting. |
| Aggressive 2 Hz | Excellent power saving setup (2 Hz rate) |
| Aggressive 4 Hz | Good power saving setup (4 Hz rate) |
| Interval | ON OFF mode setup |

u-blox recommends using these predefined settings, except where users have very specific power saving requirements.

Note that polling UBX-CFG-PMS will return the setup only if the full configuration is consistent with one of the predefined power mode setups.

🔭 In 4 Hz mode, when running a flash firmware, it is recommended to run with a subset of GNSS systems, to avoid system overload.

Using UBX-CFG-PMS to set Super-E mode to 1, 2 or 4 Hz navigation rates sets minAcqTime to 180 s instead the default 300 s in protocol version 23.01. 300 s is recommended for the best performance.

14 Forcing a Receiver Reset

Typically, in GNSS receivers, one distinguishes between cold, warm, and hot starts, depending on the type of valid information the receiver has at the time of the restart.

- Cold start In cold start mode, the receiver has no information from the last position (e.g. time, velocity, frequency etc.) at startup. Therefore, the receiver must search the full time and frequency space, and all possible satellite numbers. If a satellite signal is found, it is tracked to decode the ephemeris (18-36 seconds under strong signal conditions), whereas the other channels continue to search satellites. Once there is a sufficient number of satellites with valid ephemeris, the receiver can calculate position and velocity data. Other GNSS receiver manufacturers call this startup mode Factory Startup.
- Warm start In warm start mode, the receiver has approximate information for time, position, and coarse satellite position data (Almanac). In this mode, after power-up, the receiver normally needs to download ephemeris before it can calculate position and velocity data. As the ephemeris data usually is outdated after 4 hours, the receiver will typically start with a Warm start if it has been powered down for more than 4 hours. In this scenario, several augmentations are possible. See section Multi-GNSS assistance.
- Hot start In hot start mode, the receiver was powered down only for a short time (4 hours or less), so that its ephemeris is still valid. Since the receiver does not need to download ephemeris again, this is the fastest startup method.

In the UBX-CFG-RST message, one can force the receiver to reset and clear data, in order to see the effects of maintaining/losing such data between restarts. For this, the CFG-RST message offers the navBbrMask field, where hot, warm and cold starts can be initiated, and also other

combinations thereof.

Data stored in flash memory is not cleared by any of the options provided by UBX-CFG-RST. So, for example, if valid AssistNow Offline data stored in the flash it is likely to have an impact on the cold start.

The Reset Type can also be specified. This is not related to GNSS, but to the way the software restarts the system.

- Hardware Reset uses the on-chip Watchdog to electrically reset the chip. This is an immediate, asynchronous reset. No Stop events are generated. This is equivalent to pulling the Reset signal of the receiver to ground. This reset reloads the receiver configuration.
- Controlled Software Reset terminates all running processes in an orderly manner and, once the system is idle, restarts operation, reloads its configuration and starts to acquire and track GNSS satellites.
- Controlled Software Reset (GNSS only) only restarts the GNSS tasks, without reinitializing the full system or reloading any stored configuration.
- Controlled GNSS Stop stops all GNSS tasks. The receiver will not be restarted, but will stop any GNSS related processing.
- Controlled GNSS Start starts all GNSS tasks.

A reset may reload the receiver configuration. Use UBX-CFG-CFG to save runtime configuration changes to BBR before the reset.

15 Receiver Status Monitoring

Messages in the UBX class UBX-MON are used to report the status of the parts of the embedded computer system that are not GNSS specific.

The main purposes are

- Hardware and Software Versions, using UBX-MON-VER. See also the chapter decoding the output of UBX-MON-VER
- Status of the Communications Input/Output system
- Status of various Hardware Sections with UBX-MON-HW

15.1 Input/Output system

The I/O system is a GNSS-internal layer where all data input- and output capabilities (such as UART, DDC, SPI, USB) of the GNSS receiver are combined. Each communications task has buffers assigned, where data is queued. For data originating at the receiver, to be communicated over one or multiple communications queues, the message UBX-MON-TXBUF can be used. This message shows the current and maximum buffer usage, as well as error conditions.

If the amount of data configured is too much for a certain port's bandwidth (e.g. all UBX messages output on a UART port with a baud rate of 9600), the buffer will fill up. Once the buffer space is exceeded, new messages to be sent will be dropped. For details see section Serial Communication Ports Description.

Inbound data to the GNSS receiver is placed in buffers. Usage of these buffers is shown with the message UBX-MON-RXBUF. Further, as data is then decoded within the receiver (e.g. to separate UBX and NMEA data), the UBX-MON-MSGPP can be used. This message shows (for each port and protocol) how many messages were successfully received. It also shows (for each port) how many bytes were discarded because they were not in any of the supported protocol framings.

The following table shows the port numbers used. Note that any numbers not listed are reserved for future use.

Port Number assignment

| Port # | Electrical Interface | |
|--------|----------------------|--|
| 0 | DDC (I2C compatible) | |
| 1 | UART 1 | |
| 3 | USB | |
| 4 | SPI | |

Protocol numbers range from 0-7. All numbers not listed are reserved.

Protocol Number assignment

| Protocol# | Protocol Name | |
|-----------|---------------|--|
| 0 | UBX Protocol | |
| 1 | NMEA Protocol | |
| 2 | RTCM Protocol | |

15.2 Jamming/Interference Indicator

The field <code>jamInd</code> of the <code>UBX-MON-HW</code> message can be used as an indicator for continuous wave (narrowband) jammers/interference only. The interpretation of the value depends on the application. It is necessary to run the receiver in an unjammed environment to determine an appropriate value for the unjammed case. If the value rises significantly above this threshold, this indicates that a continuous wave jammer is present.

This indicator is always enabled.

The indicator is reporting any currently detected narrowband interference over all currently configured signal bands

15.3 Jamming/Interference Monitor (ITFM)

The field jammingState of the UBX-MON-HW message can be used as an indicator for both broadband and continuous wave (CW) jammers/interference. It is independent of the (CW only) jamming indicator described in Jamming/Interference Indicator above.

This monitor reports whether jamming has been detected or suspected by the receiver. The receiver monitors the background noise and looks for significant changes. Normally, with no interference detected, it will report 'OK'. If the receiver detects that the noise has risen above a preset threshold, the receiver reports 'Warning'. If in addition, there is no current valid fix, the receiver reports 'Critical'.

The monitor has four states as shown in the following table:

Jamming/Interference monitor reported states

| Value | Reported | Description |
|-------|----------|---|
| | state | |
| 0 | Unknown | Jamming/interference monitor not enabled, uninitialized |
| | | or antenna disconnected |
| 1 | OK | no interference detected |
| 2 | Warning | position ok but interference is visible (above the |
| | | thresholds) |

Jamming/Interference monitor reported states continued

| Value | Reported | Description |
|-------|----------|---|
| | state | |
| 3 | Critical | no reliable position fix and interference is visible (above |
| | | the thresholds); interference is probable reason why |
| | | there is no fix |

The monitor is disabled by default. The monitor is enabled by sending an appropriate UBX-CFG-ITFM message with the enable bit set. In this message it is also possible to specify the thresholds at which broadband and CW jamming are reported. These thresholds should be interpreted as the dB level above 'normal'. It is also possible to specify whether the receiver expects an active or passive antenna.

The monitor algorithm relies on comparing the currently measured spectrum with a reference from when a good fix was obtained. Thus the monitor will only function when the receiver has had at least one (good) first fix, and will report 'Unknown' before this time.

Jamming/Interference monitor is not supported in power save mode (PSM) ON/OFF mode.

The monitor is reporting any currently detected interference over all currently configured signal bands.

16 Spoofing Detection

(Note: this feature is not supported in protocol versions less than 18).

16.1 Introduction

Spoofing is the process whereby someone tries to forge a GNSS signal with the intention of fooling the receiver into calculating a different user position than the true one.

The spoofing detection feature monitors the GNSS signals for suspicious patterns indicating that the receiver is being spoofed. A flag in UBX-NAV-STATUS alerts the user to potential spoofing.

16.2 Scope

The spoofing detection feature monitors suspicious changes in the GNSS signal indicating external manipulation. Therefore the detection is only successful when the signal is genuine first and when the transition to the spoofed signal is being observed directly. When a receiver is started up to a spoofed signal the detection algorithms will be unable to recognize the spoofing. Also, the algorithms rely on availability of signals from multiple GNSS; the detection does not work in single GNSS mode.

17 Signal Attenuation Compensation

(not supported in protocol versions less than 19).

In normal operating conditions, low signal strength indicates likely contamination by multipath. The receiver trusts such signals less in order to preserve the quality of the position solution in poor signal environments. This feature can result in degraded performance in situations where the signals are attenuated for another reason, for example due to antenna placement. In this case, the signal attenuation compensation feature can be used to restore normal performance.

There are three possible modes:

- · Disabled: no signal attenuation compensation is performed
- · Automatic: the receiver automatically estimates and compensates for the signal attenuation
- · Configured: the receiver compensates for the signal attenuation based on a configured value

These modes can be selected using UBX-CFG-NAVX5. In the case of the "configured" mode, the user should input the maximum C/NO observed in a clear-sky environment, excluding any outliers or unusually high values. The configured value can have a large impact on the receiver performance, so should be chosen carefully.

18 Remote Inventory

18.1 Description

The Remote Inventory enables storing user-defined data in the non-volatile memory of the receiver. The data can be either binary or a string of ASCII characters. In the second case, it will be output at startup after the boot screen.

18.2 Usage

- The contents of the Remote Inventory can be set and polled with the message UBX-CFG-RINV. Refer to the message specification for a detailed description.
- If the contents of the Remote Inventory are polled without having been set before, the default configuration (see table below) is output.

Default configuration

| Parameter | Value |
|-----------|--------------------------|
| flags | 0x00 |
| data | "Notice: no data saved!" |

As with all configuration changes, these must be saved in order to be made permanent. Make sure to save the section RINV before resetting or switching off the receiver. For more information about saving a configuration, see section Configuration Concept.

19 Time pulse

For protocol versions less than 18, functionality of the time pulse has not been characterized when only BeiDou is enabled.

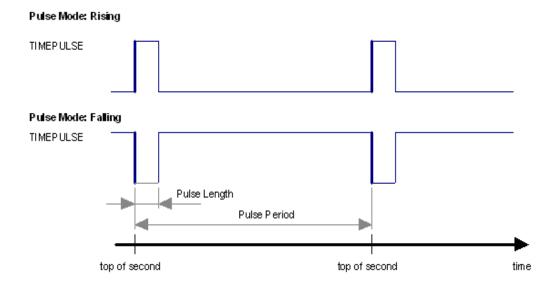

The time pulse feature is not available for protocol versions 23-23.01.

19.1 Introduction

u-blox receivers include a time pulse function providing clock pulses with configurable duration and frequency. The time pulse function can be configured using the UBX-CFG-TP5 message. The UBX-TIM-TP message provides time information for the next pulse, time source and the quantization error of the output pin.

19.2 Recommendations

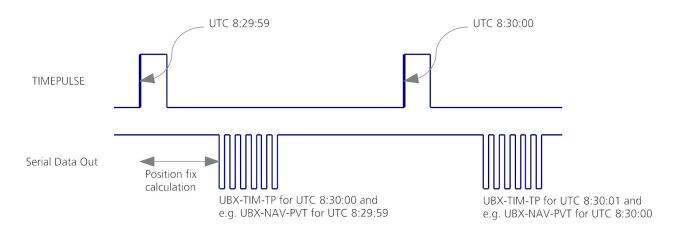

- The time pulse can be aligned to a wide variety of GNSS times or to variants of UTC derived from them (see the section on time bases). However, it is strongly recommended that the choice of time base is aligned with the available GNSS signals (so to produce GPS time or UTC(USNO), ensure GPS signals are available, and for GLONASS time or UTC(SU) ensure the presence GLONASS signals). This will involve coordinating that the setting of UBX-CFG-GNSS with the choice of time pulse time base.
- For best time pulse performance it is recommended to disable the SBAS subsystem.
- When using time pulse for precision timing applications it is recommended to calibrate the antenna cable delay against a reference-timing source.
- Care needs to be given to the cable delay settings in the receiver configuration.
- In order to get the best timing accuracy with the antenna, a fixed and accurate position is needed.
- If relative time accuracy between multiple receivers is required, do not mix receivers of different product families. If this is required, the receivers must be calibrated accordingly, by setting cable delay and user delay.
- The recommended configuration when using the UBX-TIM-TP message is to set both the measurement rate (UBX-CFG-RATE) and the time pulse frequency (UBX-CFG-TP5) to 1 Hz.

Since the rate of UBX-TIM-TP is bound to the measurement rate, more than one UBX-TIM-TP message can appear between two pulses if the measurement rate is set larger than the time pulse frequency. In this case all UBX-TIM-TP messages in between a time pulse T1 and T2 belong to T2 and the last UBX-TIM-TP before T2 reports the most accurate quantization error. In general, if the navigation solution rate and time pulse rate are configured to different values, there will not be a single UBX-TIM-TP message for each time pulse.

The sequential order of the signal present at the TIMEPULSE pin and the respective output message for the simple case of 1 pulse per second (1PPS) and a one second navigation update rate is shown in the following figure.

19.3 GNSS time bases

GNSS receivers must handle a variety of different time bases as each GNSS has its own reference system time. What is more, although each GNSS provides a model for converting their system time into UTC, they all support a slightly different variant of UTC. So, for example, GPS supports a variant of UTC as defined by the US National Observatory, while BeiDou uses UTC from the National Time Service Center, China (NTSC) and NavIC uses UTC from National Physics Laboratory, India (NPLI). While the different UTC variants are normally closely aligned, they can differ by as much as a few hundreds of nanoseconds.

Although u-blox receivers can combine a variety of different GNSS times internally, the user must choose a single type of GNSS time and, separately, a single type of UTC for input (on EXTINTs) and output (via the Time Pulse) and the parameters reported in corresponding messages.

For protocol versions 16 or greater, the UBX-CFG-TP5 message allows the user to choose between any of the supported GNSS (GPS, GLONASS, BeiDou, etc.) times and UTC. Also, the UBX-CFG-NAV5 message allows the user to select which variant of UTC the receiver should use. This includes an "automatic" option which causes the receiver to select an appropriate UTC version itself, based on the GNSS configuration, using, in order of preference, USNO if GPS is enabled, SU if GLONASS is enabled, NTSC if BeiDou is enabled, European if Galileo is enabled and, finally, NPLI if NavIC is enabled.

Note that for protocol versions prior to 16, no choice of UTC variant is supported and the UBX-CFG-TP5 message only allows the user to choose between GPS and UTC as the time system the generated time pulse will be aligned to.

The receiver will assume that the input time pulse uses the same GNSS time base as specified for the output using UBX-CFG-TP5. So if the user selects GLONASS time for time pulse output, any time pulse input must also be aligned to GLONASS time (or to the separately chosen variant of UTC). Where UTC is selected for time pulse output, any GNSS time pulse input will be assumed to be aligned to GPS time.

u-blox receivers allow users to choose independently GNSS signals used in the receiver (using UBX-CFG-GNSS) and the input/output time base (using UBX-CFG-TP5). For example it is possible to instruct the receiver to use GPS and GLONASS satellite signals to generate BeiDou time. This practice will compromise time-pulse accuracy if the receiver cannot measure the timing difference between the constellations directly and is not recommended.

The information that allows GNSS times to be converted to the associated UTC times is

only transmitted by the GNSS at relatively infrequent periods. For example GPS transmits UTC(USNO) information only once every 12.5 minutes. Therefore, if a Time Pulse is configured to use a variant of UTC time, after a cold start, substantial delays before the receiver has sufficient information to start outputing the Time Pulse can be expected.

19.4 Time pulse configuration

u-blox receivers provide one or two TIMEPULSE pins (dependent on product variant) delivering a time pulse (TP) signal with a configurable pulse period, pulse length and polarity (rising or falling edge). Check the product data sheet for detailed specification of configurable values.

It is possible to define different signal behavior (i.e. output frequency and pulse length) depending on whether or not the receiver is locked to a reliable time source. Time pulse signals can be configured using the UBX proprietary message UBX-CFG-TP5.

19.5 Configuring time pulse with UBX-CFG-TP5

The UBX message UBX-CFG-TP5 can be used to change the time pulse settings, and includes the following parameters defining the pulse:

- time pulse index Index of time pulse output pin to be configured. If a product only has one time pulse output it is typically configurable with index 0. Exceptions to this include LEA-M8F, M8030-KT-FT and NEO-M8L. Refer to specific product documentation.
- antenna cable delay Signal delay due to the cable between antenna and receiver.
- RF group delay Signal delay in the RF module of the receiver (read-only).
- **pulse frequency/period** Frequency or period time of the pulse when locked mode is not configured or active.
- pulse frequency/period lock Frequency or period time of the pulse, as soon as receiver has calculated a valid time from a received signal. Only used if the corresponding flag is set to use another setting in locked mode.
- pulse length/ratio Length or duty cycle of the generated pulse, either specifies a time or ratio for the pulse to be on/off.
- pulse length/ratio lock Length or duty cycle of the generated pulse, as soon as receiver has calculated a valid time from a received signal. Only used if the corresponding flag is set to use another setting in locked mode.
- **user delay** The cable delay from the receiver to the user device plus signal delay of any user application.
- active time pulse will be active if this bit is set.
- lock to gps freq Use frequency gained from GPS signal information rather than local oscillator's frequency if flag is set.
- **lock to gnss freq** Use frequency gained from GNSS signal information rather than local oscillator's frequency if flag is set.
- **locked other setting** If this bit is set, as soon as the receiver can calculate a valid time, the alternative setting is used. This mode can be used for example to disable time pulse if time is not locked, or indicate lock with different duty cycles.
- is frequency Interpret the 'Frequency/Period' field as frequency rather than period if flag is set.
- is length Interpret the 'Length/Ratio' field as length rather than ratio if flag is set.

- align to TOW If this bit is set, pulses are aligned to the top of a second.
- polarity If set, the first edge of the pulse is a rising edge (Pulse Mode: Rising).
- grid UTC/GPS Selection between UTC (0) or GPS (1) timegrid. Also effects the time output by UBX-TIM-TP message.
- grid UTC/GNSS Selection between UTC (0), GPS (1), GLONASS (2) and Beidou (3) timegrid. Also effects the time output by UBX-TIM-TP message.

The maximum pulse length can't exceed the pulse period.

Time pulse settings shall be chosen in such a way, that neither the high nor the low period of the output is less than 50 ns (except when disabling it completely), otherwise pulses can be lost.

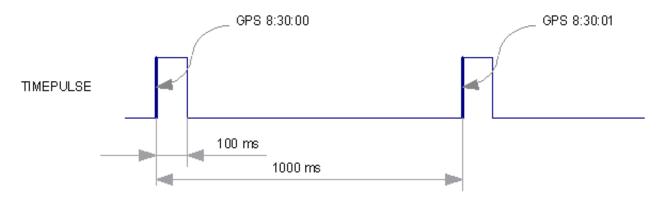

The maximum frequency of the second time pulse pin (TIMEPULSE2) is limited to 1 kHz for protocol versions less than 18 unless using a Timing product variant.

19.5.1 Example 1

The example below shows the 1PPS TP signal generated on the time pulse output according to the specific parameters of the UBX-CFG-TP5 message:

- tpldx = 0
- freqPeriod = 1 s
- pulseLenRatio = 100 ms
- active = 1
- lockGpsFreq = lockGnssFreq = 1
- isLength = 1
- alignToTow = 1
- polarity = 1
- gridUtcGps = gridUtcGnss = 1

The 1 Hz output is maintained whether or not the receiver is locked to GPS time. The alignment to TOW can only be maintained when GPS time is locked.

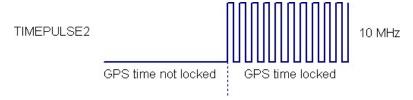

19.5.2 Example 2

This example only works with a Timing product variant or for protocol versions greater than 17.

The following example shows a 10 MHz TP signal generated on the TIMEPULSE2 output when the receiver is locked to GPS time. Without the lock to GPS time no frequency is output.

- tpldx = 1
- freqPeriod = 1 Hz
- pulseLenRatio = 0
- freqPeriodLock = 10 MHz
- pulseLenRatioLock = 50%
- active = 1
- lockGpsFreq = lockGnssFreq = 1
- lockedOtherSet = 1
- isFreq = 1
- alignToTow = 1
- polarity = 1
- gridUtcGps = gridUtcGnss = 1

20 Timemark

The receiver can be used to provide an accurate measurement of the time at which a pulse was detected on the external interrupt pin. The reference time can be chosen by setting the time source parameter to UTC, GPS, GLONASS, BeiDou, Galileo or local time in the UBX-CFG-TP5 configuration message. The UTC standard can be set in the UBX-CFG-NAV5 configuration message. The delay figures defined with UBX-CFG-TP5 are also applied to the results output in the UBX-TIM-TM2 message.

A UBX-TIM-TM2 message is output at the next epoch if

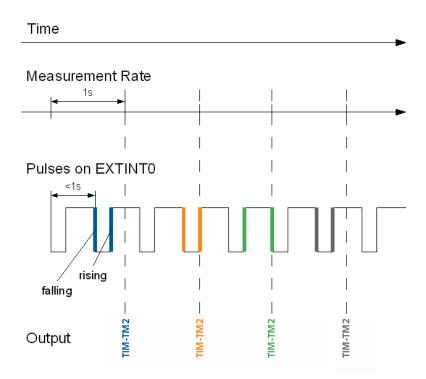

- the UBX-TIM-TM2 message is enabled
- a rising or falling edge was triggered since last epoch on one of the EXTINT channels

The UBX-TIM-TM2 messages include time of the last timemark, new rising/falling edge indicator, time source, validity, number of marks and a quantization error. The timemark is triggered continuously.

Only the last rising and falling edge detected between two epochs is reported since the output rate of the UBX-TIM-TM2 message corresponds to the measurement rate configured with UBX-CFG-RATE (see Figure below).

21 Odometer

21.1 Introduction

The odometer provides information on travelled ground distance (in meter) using solely the position and Doppler-based velocity of the navigation solution. For each computed travelled distance since the last odometer reset, the odometer estimates a 1-sigma accuracy value. The total cumulative ground distance is maintained and saved in the BBR memory.

The odometer feature is disabled by default. It can be enabled using the UBX-CFG-ODO message.

21.2 Odometer Output

The odometer output is published in the UBX-NAV-ODO message. This message contains the following elements:

- Ground distance since last reset (distance field): this distance is defined as the total cumulated distance in meters since the last time the odometer was reset (see section Resetting the Odometer);
- Ground distance accuracy (distanceStd field): this quantity is defined as the 1-sigma accuracy estimate (in meters) associated to the Ground distance since last reset value;
- Total cumulative ground distance (totalDistance field): this quantity is defined as the total cumulated distance in meters since the last time the receiver was cold started (see section Resetting the Odometer).

If logging is enabled, then the odometer's ground distance since last reset value will be included in

the logged position data (see section Logging).

21.3 Odometer Configuration

The odometer can be enabled/disabled by setting the appropriate flag in UBX-CFG-ODO (flags field). The algorithm behaviour can be optimized by setting up a profile (odoCfg field) representative of the context in which the receiver is operated. The implemented profiles together with their meanings are listed below:

- Running: the algorithm is optimized for typical dynamics encountered while running, i.e the Doppler-based velocity solution is assumed to be of lower quality;
- Cycling: the algorithm is optimized for typical dynamics encountered while cycling;
- Swimming: the algorithm is optimized for very slow and smooth trajectories typically encountered while swimming;
- Car: the algorithm assumes that good Doppler measurements are available (i.e. the antenna is subject to low vibrations) and is optimized for typical dynamics encountered by cars.

The odometer can only be reliably operated in a swimming context if satellite signals are available and the antenna is not immersed.

21.4 Resetting the Odometer

The odometer outputs (see UBX-NAV-ODO message) can be reset by the following means:

- Ground distance since last reset (distance field): by sending a UBX-NAV-RESETODO message;
- Ground distance accuracy (distanceStd field): by sending a UBX-NAV-RESETODO message;
- Total cumulative ground distance (totalDistance): by a cold start of the receiver (this erases the BBR memory);

22 Logging

22.1 Introduction

The logging feature allows position fixes and arbitrary byte strings from the host to be logged in flash memory attached to the receiver. Logging of position fixes happens independently of the host system, and can continue while the host is powered down.

The following tables list all the logging related messages:

Logging control and configuration messages

| Message | Description |
|-------------------|--|
| UBX-LOG-CREATE | Creates a log file and activates the logging subsystem |
| UBX-LOG-ERASE | Erases a log file and deactivates the logging subsystem |
| UBX-CFG-LOGFILTER | Used to start/stop recording and set/get the logging configuration |
| UBX-LOG-INFO | Provides information about the logging system |
| UBX-LOG-STRING | Enables a host process to write a string of bytes to the log file |

Logging retrieval messages

| Message | Description |
|---------------------|---|
| UBX-LOG-RETRIEVE | Starts the log retrieval process |
| UBX-LOG-RETRIEVEPOS | A position log entry returned by the receiver |

Logging retrieval messages continued

| Message | Description |
|------------------------|--|
| UBX-LOG- | Odometer position data |
| RETRIEVEPOSEXTRA | |
| UBX-LOG-RETRIEVESTRING | A byte string log entry returned by the receiver |
| UBX-LOG-FINDTIME | Finds the index of the first entry <= given time |

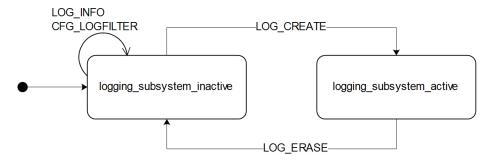

22.2 Setting the logging system up

An empty log can be created using the UBX-LOG-CREATE message and a log can be deleted with the UBX-LOG-ERASE message. The logging system will only be running if a log is in existence, so most logging messages will be rejected with an UBX-ACK-NAK message if there is no log present. Only one log can be created at any one time so an UBX-ACK-NAK message will be returned if a log already exists. The message specifies the maximum size of the log in bytes (with some pre-set values provided). Both the logging subsystem and the receiver file-store have implementation overheads, so total space available for log entries will be somewhat smaller than the size specified.

UBX-LOG-CREATE also allows the log to be specified as a circular log. If the log is circular, then when it fills up, a set of older log entries will be deleted and the space freed up used for new log entries. By contrast, if a non-circular log becomes full then new entries which do not fit will be rejected. UBX-LOG-CREATE also causes the logging system to start up so that further logging messages can be processed. The logging system will start up automatically on power-up if there is a log in existence. The log will remain in the receiver until specifically erased using the UBX-LOG-ERASE message.

UBX-CFG-LOGFILTER controls whether logging of entries is currently enabled and selects position fix messages for logging. These configuration settings will be saved if the configuration is saved to flash. If this is done, then entry logging will continue on power-up in the same manner that it did before power-down.

The top level active/inactive states of the logging subsystem.

22.3 Information about the log

The receiver can be polled for a UBX-LOG-INFO message which will give information about the log. This will include the maximum size that the log can grow to (which, due to overheads, will be smaller than that requested in UBX-LOG-CREATE) and the amount of log space currently occupied. It will also report the number of entries currently in the log together with the time and date of the newest and oldest messages which have a valid time stamp.

Log entries are compressed and have housekeeping information associated with them, so the actual space occupied by log messages may be difficult to predict. The minimum size for a

position fix entry is 9 bytes and the maximum 24 bytes, the typical size is 10 or 11 bytes. If the odometer is enabled then this will use at least another three bytes per fix.

Each log also has a fixed overhead which is dependent on the log type. The approximate size of this overhead is shown in the following table.

Log overhead size

| Log type | Overhead |
|--------------|-------------|
| circular | Up to 40 kB |
| non-circular | Up to 8 kB |

The number of entries that can be logged in any given flash size can be estimated as follows:

Approx. number of entries = (flash size available for logging - log overhead)/typical entry size

For example, if 1500 kB of flash is available for logging (after other flash usage such as the firmware image is taken into account) a non-circular log would be able to contain approximately 139000 entries ((1500*1024)-(8*1024))/11 = 138891.

22.4 Recording

The UBX-CFG-LOGFILTER message specifies the conditions under which entries are recorded. Nothing will be recorded if recording is disabled, otherwise position fix and UBX-LOG-STRING entries can be recorded. When recording is enabled an entry will also be created from each UBX-LOG-STRING message. These will be timestamped if the receiver has current knowledge of time.

The UBX-CFG-LOGFILTER message has several values which can be used to select position fix entries for logging. If all of these values are zero, then all position fixes will be logged (subject to a maximum rate of 1Hz). A position is logged if any of the thresholds are exceeded. If a threshold is set to zero it is ignored. In addition the position difference and current speed thresholds also have a minimum time threshold.

Position fixes are only recorded if a valid fix is obtained - failed and invalid fixes are not recorded.

Position fixes are compressed to economise on the amount of flash space used. In order to improve the compression, the fix values are rounded to improve their compression. This means that the values returned by the logging system may differ slightly from any which are gathered in real time.

In On/Off power save mode it is possible to configure the logging system so that only one fix is recorded for each on period. This will be recorded immediately before the receiver powers off and will be the best fix seen during the on period (in this case, "best" is defined as being the fix with the lowest horizontal accuracy figure).

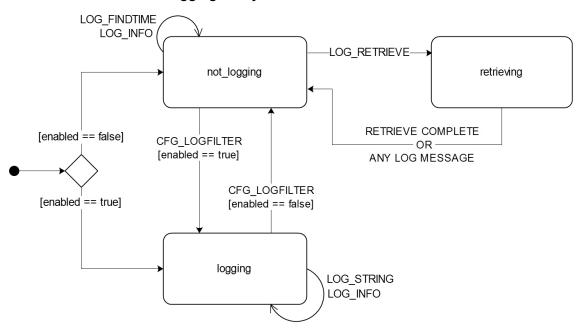

The recorded data for a fix comprises:

- The time and date of the fix recorded to a precision of one second.
- Latitude and longitude to a precision of one millionth of a degree. Depending on position on Earth this is a precision in the order of 0.1 m.
- Altitude (height above mean sea level) to a precision of 0.1 m. Entries with an altitude lower than
 -470 m (lower than the lowest point on earth) or higher than 20,000 m may not be recorded in
 the log.
- Ground speed to a precision of 1 cm/s
- The fix type (only successful fix types, since these are the only ones recorded).

- The number of satellites used in the fix is recorded, but there is a maximum count which can be recorded. If the actual count exceeds this maximum count then the maximum count will be recorded. If a log entry is retrieved with a satellite count equal to the maximum this means that value or more. The maximum count is 51. (The maximum count is 19 in protocol versions less than 24).
- A horizontal accuracy estimate is recorded to give an indication of fix quality. This is an
 approximate compressed representation of the accuracy as determined by the fix process. Any
 accuracy less than 0.7 m will be recorded as 0.7 m and any value above 1 km will be recorded as
 1km. Within these limits, the recorded accuracy will always be greater than the fix accuracy
 number (by up to 40%).
- · Heading to a precision of one degree.
- Odometer distance data (if odometer is enabled).

The states of the active logging subsystem

22.5 Retrieval

UBX-LOG-RETRIEVE starts the process which allows the receiver to output log entries. Log recording must be stopped using UBX-CFG-LOGFILTER before this can be done. UBX-LOG-INFO may be helpful to a host system in order to understand the current log status before retrieval is started.

Once retrieval has started, one message will be output from the receiver for each log entry requested. Sending any logging message to the receiver during retrieval will cause the retrieval to stop before the message is processed.

To maximise the speed of transfer it is recommended that a high communications data rate is used and GNSS processing is stopped during the transfer (see UBX-CFG-RST)

UBX-LOG-RETRIEVE can specify a start-entry index and entry-count. The maximum number of entries that can be returned in response to a single UBX-LOG-RETRIEVE message is 256. If more entries than this are required the message will need to be sent multiple times with different startEntry indices.

The receiver will send a UBX-LOG-RETRIEVEPOS message for each position fix log entry and a UBX-LOG-RETRIEVESTRING message for each string log entry. If the odometer was enabled at the time a position was logged, then a UBX-LOG-RETRIEVEPOSEXTRA will also be sent. Messages will be sent in the order in which they were logged, so UBX-LOG-RETRIEVEPOS and UBX-LOG-RETRIEVESTRING messages may be interspersed in the message stream.

The UBX-LOG-FINDTIME message can be used to search a log for the index of the first entry less than or equal to the given time. This index can then be used with the UBX-LOG-RETRIEVE message to provide time-based retrieval of log entries.

22.6 Command message acknowledgement

Some log operations may take a long time to execute because of the time taken to write to flash memory. The time for some operations may be unpredictable since the number and timing of flash operations may vary. In order to allow host software to synchronise to these delays logging messages will always produce a response. This will be UBX-ACK-NAK in case of error, otherwise UBX-ACK-ACK unless there is some other defined response to the message.

It is possible to send a small number of logging commands without waiting for acknowledgement, since there is a command queue, but this risks confusion between the acknowledgements for the commands. Also a command queue overflow would result in commands being lost.

23 Data Batching

(Note: this functionality is supported only in protocol versions 23.01).

23.1 Introduction

The data batching feature allows position fixes to be stored in the RAM of the receiver to be retrieved later in one batch. Batching of position fixes happens independently of the host system, and can continue while the host is powered down.

The following tables list all the batching related messages:

Batching control and configuration messages

| Message | Description |
|---------------|---|
| UBX-CFG-BATCH | Used to enable and configure the batching feature |
| UBX-MON-BATCH | Provides information about the buffer fill level and dropped data due |
| | to overrun |

Batch retrieval messages

| Message | Description |
|-----------------------|--|
| UBX-LOG-RETRIEVEBATCH | Starts the batch retrieval process |
| UBX-LOG-BATCH | A batch entry returned by the receiver |

23.2 Setting up the data batching

Data batching is disabled per default and it has to be configured before use via UBX-CFG-BATCH.

The feature must be enabled and the buffer size must be set to greater than 0. It is possible to set up a PIO as a flag that indicates when the buffer is close to filling up. The fill level when this PIO is asserted can be set by the user separately from the buffer size. The notification fill level must not be larger than the buffer size.

If the host does not retrieve the batched fixes before the buffer fills up the oldest fix will be

dropped and replaced with the newest.

The RAM available in the chip limits the size of the buffer. To make the best use of the available space users can select what data they want to batch. When batching is enabled a basic set of data is stored and the configuration flags <code>extraPvt</code> and <code>extraOdo</code> can be used to store more detailed information about the position fixes. Doing so reduces the number of fixes that can be batched.

The receiver will reject configuration if it cannot allocate the required buffer memory. To ensure robust operation of the receiver the following limits are enforced:

Maximum number of batched epochs

| extraPvt | extraOdo | Maximum number of epochs |
|----------|----------|--------------------------|
| 0 | 0 | 300 |
| 0 | 1 | 221 |
| 1 | 0 | 156 |
| 1 | 1 | 132 |

It is recommended to disable all periodic output messages when using batching. This improves system robustness and also helps ensure that the output of batched data is not delayed by other messages.

The buffer size is set up in terms of navigation epochs. This means that the time that can be covered with a certain buffer depends on the navigation rate. This rate can be set separately for full power operation via UBX-CFG-RATE and for power save mode via the updatePeriod in UBX-CFG-PM2.

Data batching settings should not be re-configured while retrieving data from the buffer.

23.3 Retrieval

UBX-LOG-RETRIEVEBATCH starts the process which allows the receiver to output batch entries. Batching must not be stopped for readout; all batched data is lost when the feature is disabled.

Batched fixes are always retrieved starting with the oldest fix in the buffer and progressing towards newer ones. There is no way to skip certain fixes during retrieval.

When a UBX-LOG-RETRIEVEBATCH message is sent the receiver transmits all batched fixes. It is recommended to send a retrieval request with sendMonFirst set. This way the receiver will send a UBX-MON-BATCH message first that contains the number of fixes in the batching buffer. This information can be used to detect when the u-blox receiver finished sending data.

Once retrieval has started, the receiver will first send UBX-MON-BATCH if sendMonFirst option was selected in the UBX-LOG-RETRIEVEBATCH. After that, it will send UBX-LOG-BATCH messages with the batched fixes.

To maximise the speed of transfer it is recommended that a high communications data rate is used.

The receiver will discard retrieval request while processing a previous UBX-LOG-RETRIEVEBATCH message.

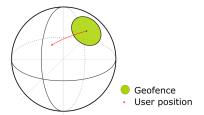

The receiver does **not** acknowledge the reception of UBX-LOG-RETRIEVEBATCH; the response that the host should expect are the reply messages.

24 Geofencing

(Note: this feature is not supported in protocol versions less than 18).

24.1 Introduction

The geofencing feature allows for the configuration of up to four circular areas (geofences) on the Earth's surface. The receiver will then evaluate for each of these areas whether the current position lies within the area or not and signal the state via UBX messaging and PIO toggling.

24.2 Interface

Geofencing can be configured using the UBX-CFG-GEOFENCE message. The geofence evaluation is active whenever there is at least one geofence configured.

The current state of each geofence plus the combined state is output in UBX-NAV-GEOFENCE with every navigation epoch.

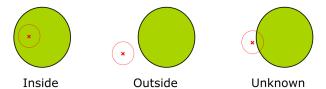

Additionally the user can configure the receiver to output the combined geofence state on a physical pin.

24.3 Geofence state evaluation

With every navigation epoch the receiver will evaluate the current solution's position versus the configured geofences. There are three possible outcomes for each geofence:

- Inside The position is inside the geofence with the configured confidence level
- Outside The position lies outside of the geofence with the configured confidence level
- Unknown There is no valid position solution or the position uncertainty does not allow for unambiguous state evaluation

The position solution uncertainty (standard deviation) is multiplied with the configured confidence sigma level number and taken into account when evaluating the geofence state (red circle in figure below).

The combined state for all geofences is evaluated as the combination (logical OR) of all geofences:

- Inside The position lies inside of at least one geofence
- Outside The position lies outside of all geofences
- Unknown All remaining states

24.4 Using a PIO for Geofence State Output

This feature can be used for example for waking up a sleeping host when a defined geofence condition is reached. The receiver will toggle the assigned pin according to the combined geofence state. Due to hardware restrictions the unknown state will always be represented as HIGH. If the receiver is in software backup or in a reset, the pin will go to HIGH accordingly. The meaning of the LOW state can be configured using UBX-CFG-GEOFENCE.

25 Time Mode Configuration

This feature is only available with Timing, FTS or High Precision GNSS (HPG) products

This section relates to the configuration message UBX-CFG-TMODE2 (for Timing or FTS products) and to the configuration message UBX-CFG-TMODE3 (for HPG products).

25.1 Introduction

Time Mode is a special receiver mode where the position of the receiver is known and fixed and only the time is calculated using all available satellites. This mode allows for maximum time accuracy, for single-SV solutions, and also for using the receiver as a stationary reference station.

25.2 Fixed Position

In order to use the Time Mode, the receiver's position must be known as exactly as possible. Either the user already knows and enters the position, or it is determined using Survey-in. Errors in the fixed position will translate into time errors depending on the satellite constellation.

For Timing products, as a rule of thumb the position should be known with an accuracy of better than 1 m for a timing accuracy in the order of nanoseconds. If an accuracy is required only in the order of microseconds, a position accuracy of roughly 300 m is sufficient.

For HPG products, errors in the reference station position will directly translate into rover position errors. The reference station position accuracy should therefore be at least as good as the desired rover absolute position accuracy.

25.3 Survey-in

Survey-in is the procedure that is carried out prior to using Time Mode. It determines a stationary receiver's position by building a weighted mean of all valid 3D position solutions.

Two requirements for stopping the procedure must be specified:

- The **minimum observation time** defines a minimum amount of observation time regardless of the actual number of valid fixes that were used for the position calculation. Reasonable values range from one day for high accuracy requirements to a few minutes for coarse position determination.
- The **required 3D position standard deviation** defines a limit on the spread of positions that contribute to the calculated mean. As the position error translates into a time error when using Time Mode (see above), one should carefully evaluate the time accuracy requirements and choose an appropriate value.

Survey-in ends, when **both** requirements are met. After Survey-in has finished successfully, the receiver will automatically enter fixed position Time Mode.

The Survey-in status can queried using the UBX-TIM-SVIN message for Timing or FTS products or

the UBX-NAV-SVIN message for HPG products.

The "Standard Deviation" parameter defines uncertainty of the manually provided "True Position" set of parameters. This uncertainty directly affects the accuracy of the timepulse. This is to prevent an error that would otherwise be present in the timepulse because of the initially inaccurate position (assumed to be correct by the receiver) without users being aware of it. The "3D accuracy" parameter in "Fixed Position" as well as the "Position accuracy limit" in "Survey-in" affect the produced time information and the timepulse in the same way. Note that the availability of the position accuracy does not mitigate the error in the timepulse but only accounts for it when calculating the resulting time accuracy.

Once a survey-in has been started, its progress is saved in non-volatile memory, and hence continues over events such as a reset, receiver restart, or change of satellite constellation. If a survey-in position is required using data only for a particular receiver configuration, then any on-going survey-in should be stopped by either a UBX-CFG-TMODE2 or a UBX-CFG-TMODE3 message with the timeMode field set to 0, then the receiver configured as required, and then a new UBX-CFG-TMODE2 or UBX-CFG-TMODE3 message sent with the new survey-in parameters.

26 Time & Frequency Sync (FTS)

The features described in this section are only available with the FTS products

26.1 Introduction

An FTS configured receiver provides an accurate, low phase-noise reference frequency as well as phase reference pulse (typically at one pulse per second). An FTS receiver also implements automatic hold-over capability based on a stable VCTCXO in modules and the customer's choice of reference oscillator in chip-based designs. It offers generic interfaces for external sources of synchronization (suitable for external OCXOs, IEEE1588 or Synchronous Ethernet). The receiver is optimized for stationary applications and delivers excellent GNSS sensitivity in conjunction with assistance data.

In the rest of this description the following terminology will be used:

- Disciplined oscillator: an oscillator whose frequency is corrected by a more stable frequency reference, such as a GNSS system.
- Internal oscillator: the mandatory disciplined oscillator which is used as the reference frequency for the GNSS receiver subsystem. The output from this oscillator is also available to the application as an output from the module.
- External oscillator: an optional oscillator, disciplined by the receiver, either via I2C DAC or via UBX messages handle by a host.
- Source: a source of frequency and/or phase synchronization either measured by the receiver based on direct hardware input or an offset estimated by an external timing sub-system with respect to the receiver output. Sources are handled according to related estimates of uncertainty delivered by the application or (for oscillators) configurable models provided by the receiver.
- Holdover: periods when GNSS measurements of sufficient quality to maintain time/frequency are not available.

In all FTS related messages the above sources are indexed as follows:

Synchronization source indexing

| Source | Index |
|-------------------------------------|-------|
| Internal oscillator | 0 |
| GNSS | 1 |
| EXTINTO (external input) | 2 |
| EXTINT1 (external input) | 3 |
| Internal oscillator measured by the | 4 |
| host | |
| External oscillator measured by the | 5 |
| host | |

The following table lists FTS related messages:

FTS message summary

| Message | Description |
|----------------|--|
| UBX-CFG-SMGR | Synchronization manager configuration |
| UBX-CFG-ESRC | External source configuration |
| UBX-CFG-DOSC | Disciplined oscillator configuration |
| UBX-CFG-TP5 | Configures the output pulse parameters |
| UBX-CFG-NAV5 | Configures which variant of UTC is used by the receiver |
| UBX-MON-SMGR | SMGR monitoring message |
| UBX-TIM-DOSC | Message containing disciplining command for external oscillators |
| | controlled through the host |
| UBX-TIM-HOC | Message allowing the host to directly control the module's |
| | oscillators |
| UBX-TIM-TOS | Message containing information about the preceding time-pulse |
| | output by the receiver |
| UBX-TIM-SMEAS | Message containing measurements of phase/frequency inputs |
| UBX-TIM-VCOCAL | Oscillator calibration command and result report |
| UBX-TIM-FCHG | Information about latest frequency change to an oscillator |

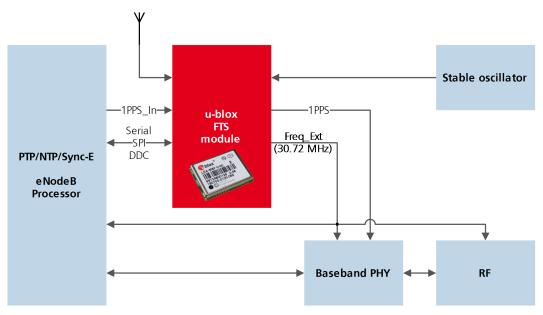

The remainder of this chapter describes some typical use cases, introduces the Synchronization Manager (SMGR) functionality unique to FTS products and describes the use of related messages.

26.2 Example use cases

In this section some typical use cases are described.

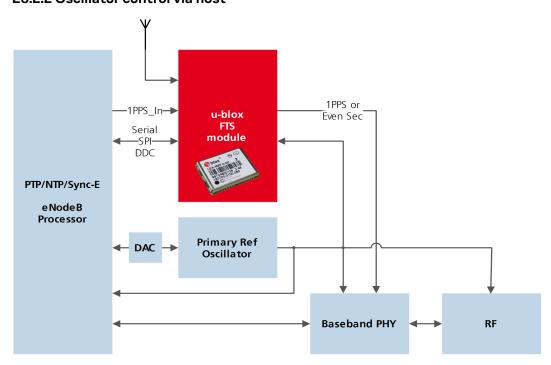

26.2.1 Stand-alone synchronization system

In this example, the FTS device provides a stand-alone synchronization sub-system in the context of, say, a small cell. The module's internal 30.72MHz VCTCXO is disciplined by the module and provides the frequency reference to the platform. The module provides a PPS signal to synchronize the platform's physical layer. A 1PPS (or frequency) input to the module provides frequency and/or phase information from host timing sub-systems such as PTP or Sync-E. In the absence of phase information from GNSS or any other source, the module relies on the VCTCXO for synchronization holdover, augmented by any reliable source of frequency control. In the absence of frequency control, the holdover performance is determined entirely by the VCTCXO. In some applications holdover performance will be enhanced by using an external stable (but not necessarily accurate) frequency reference.

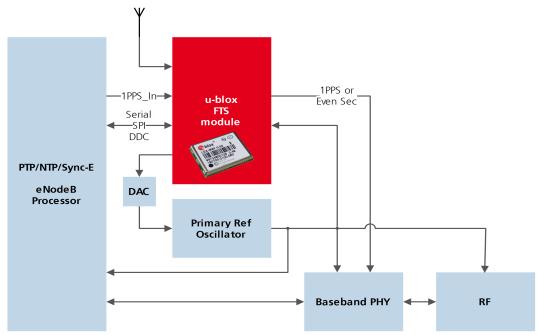

26.2.2 Oscillator control via host

The frequency offset of the external oscillator is measured by the FTS device and communicated to the host which can then make any corrections necessary. The FTS device also generates a PPS phase reference internally (with no guarantee of coherence with the external oscillator). During holdover, the phase of 1PPS signal is maintained using either the primary reference oscillator or the 1PPS_In signal, according to their respective uncertainty.

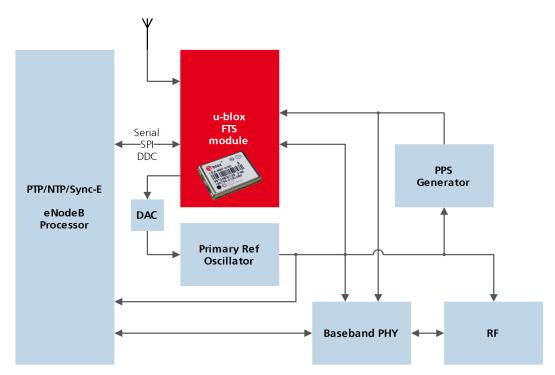

26.2.3 Oscillator control via directly-connected DAC

In this use case, the FTS device disciplines an external oscillator via an external DAC. During holdover the input to the external DAC is frozen and the phase of the time pulse output is maintained by the primary reference oscillator, but only guaranteed to be fully coherent with the internal oscillator. The FTS receiver can also be commanded to perform a one-off calibration of the tuning slope of external oscillator if necessary.

26.2.4 External (coherent) PPS

In this use case, the system PPS is generated by an external device from the output of the primary reference oscillator. The FTS receiver measures the phase of this PPS input against GNSS time or the best available source. Any small phase corrections necessary can be made by the receiver via adjustments to the oscillator frequency or directly by the host to the PPS generator (e.g. to accelerate removal of large phase errors). During holdover the DAC input is frozen.

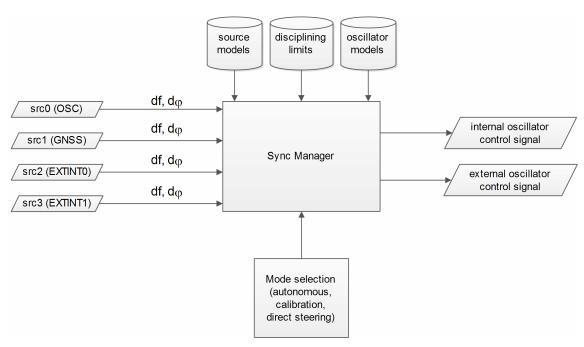

26.3 Synchronization Manager Concept

The Synchronization Manager (SMGR) assumes the frequency and phase control functions in FTS configured devices. The SMGR uses internal and external phase and frequency measurements to derive the disciplining values (necessary frequency changes) and to assess the quality (uncertainty) of the time pulse signal and the frequency outputs. The SMGR considers the following synchronization sources:

- The GNSS solutions
- Internal oscillator
- Up to two external signals: frequency or time pulse (e.g. 1PPS) reference signals on EXTINTO and/or EXTINT1
- Externally conducted measurements, from which the results are sent to the receiver through one of the host interfaces

Each measurement provides frequency offset and/or phase information along with an estimate of the uncertainty of each. The SMGR functional block diagram is given below:

The user has the option to configure how the SMGR considers the external signals, e.g. time or frequency source, disciplined or not, etc... The user must also configure the uncertainty of the signals along with their nominal characteristics. One of the external signals may be configured as the feedback path of a disciplined external oscillator.

The SMGR can operate in frequency locked or in phase locked mode. In frequency locked mode the target of the SMGR is to eliminate frequency error. In phase locked mode the elimination of time error is the goal; this may lead to intentional deviation from the correct oscillator frequency. The correction rate in both of these modes is subject to configurable limits (see UBX-CFG-SMGR). The SMGR runs periodically (typically once a second). Its operation consists of the following stages each time it is executed:

- Choose the best source to be the reference, given the characteristics (phase noise and stability) of each of the sources and the uncertainty of their measurements.
- Calculate the phase and/or frequency errors as well as their uncertainty for each of the disciplined oscillators with respect to the reference source.
- Calculate correction for disciplined oscillators; time and/or frequency corrections are limited to the configured limits.
- Map frequency adjustment to physical output.

The SMGR runs periodically and retrieves the most recent measurements for each source along with the estimates about their respective uncertainty. The relative phase and/or frequency errors of disciplined oscillators with respect to the reference are calculated from incoming measurements and used to discipline them. The decision-making process as such does not depend on decisions made previously, however it does rely on the estimated uncertainty for each source, which is determined by comparing predicted and measured values over some moderate period of time. The SMGR only uses a single reference source at any one time. It does not combine measurements from different sources in any way. If the selected reference provides a time error measurement then a phase locked loop is possible, otherwise the receiver automatically enters frequency lock even if configured to maintain a phase lock.

In some cases the host software might choose to drive an oscillator directly. This may be useful

where a large timing error has accumulated (e.g. after a long period of holdover) and normal operation would prevent the error being corrected swiftly. In this case, the host can deliberately steer the oscillator to correct timing in large steps as configured maximum phase and frequency change limits are not applied to adjustments commanded by the host. Another use of the direct host-driven steering may be the calibration of other parts of the system. Use UBX-TIM-HOC message for this functionality.

If the time error is so large that its correction would take prohibitively long even with maximum frequency offset of the oscillator the receiver can be switched to non-coherent time pulse output mode. In this case the sync manager is temporarily reconfigured to allow time pulse intervals that are not coherent with the frequency output, i.e. there are more or less than the nominal number of cycles between two pulses. The user may optionally specify a limit on time adjustments. The output mode can be set to coherent again once the time error is sufficiently small.

A SMGR summary status is provided by UBX-MON-SMGR message.

The SMGR runs at the navigation rate set by UBX-CFG-RATE. For FTS configured devices, it is not recommended to use navigation rates higher than 1Hz.

26.4 Oscillator and source specification

For correct operation, the frequency, phase and stability characteristics of all sources and disciplined oscillators must be described. External synchronization sources are configured with UBX-CFG-ESRC and disciplined oscillators with UBX-CFG-DOSC. The models (short and long term stability behavior) specified by these messages provide the SMGR with the knowledge necessary to its decision making.

The user must also configure the method (coherent or non-coherent) used for frequency adjustment, the maximum frequency adjustment and other parameters contained in UBX-CFG-DOSC.

It is assumed that an external voltage-controlled oscillator has a constant ratio of relative frequency change to control voltage change. The oscillator is therefore characterized by two metrics: an offset (control voltage for nominal frequency) and a gain (relative frequency change per control step). Each of these parameters are known along with their uncertainty. It is assumed that the oscillator control gain is stable over time but its offset may change significantly with aging. Because of the drift of the offset, its saved value is regularly updated in the model. The gain, on the other hand, is only updated on demand by the host application by re-configuration or calibration. For the measurement of the gain a special auto-calibration is available, described in the calibration section.

External oscillator stability (frequency changes) is described by four parameters (see UBX-CFG-DOSC):

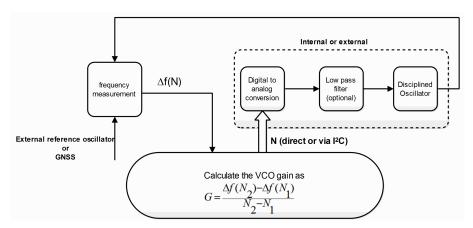

- changes with temperature: withTemp is the maximum deviation limit from the nominal frequency at the reference temperature over the supported temperature range (in ppb) and timeToTemp (in s) which is a period after which the maximum deviation limit is reached.
- aging: maxDevLifeTime is the maximum deviation from the nominal frequency (in ppb) and withAge is the oscillator stability with age (in ppb/year).

26.5 Calibration

Prior to disciplining an oscillator, the SMGR must have an accurate knowledge of the controlled oscillator's frequency control gain and initial frequency offset (oscillator gains may differ significantly from unit to unit and batch to batch, largely as a result of different crystal Q). The receiver provides a slope measurement utility to aid the calibration process.

The calibration utility is a special mode where all disciplining operations are suspended and therefore all disciplined oscillators, internal or external, cease to produce usable outputs. It takes place in response to a specific request (UBX-TIM-VCOCAL message) from the host to do so for a particular oscillator and only one oscillator can be calibrated at a time. During this phase, the SMGR forces large frequency variations by changing the input of the digital to analogue conversion device whose output is driving the oscillator. Several frequency measurements are performed and a gain is estimated.

Calibration parameters must be configured or the calibration utility called before disciplining operation is possible. Once calibrated, the calibStatus flag in UBX-CFG-DOSC is set. The calibration utility can be re-triggered at any time by issuing the appropriate command through the UBX-TIM-VCOCAL message (not recommended during normal operation). An ongoing calibration process can be aborted using the same message with the appropriate flags. It can also be bypassed if the calibStatus flag in the UBX-CFG-DOSC message is set to 1 (oscillator is calibrated independently with results saved using the UBX-CFG-DOSC message).

In order to enter the calibration mode it is required that:

- A stable frequency source is available for the duration of the calibration. This source may be a GNSS solution or a frequency signal on an EXTINT pin.
- The oscillator subject to calibration is configured through the UBX-CFG-DOSC message (including an initial estimate of gain) and available for the duration of the process.

For an external oscillator it is also assumed that the useful range of the input is covered by the output of the DAC and that the relation frequency versus DAC input is linear. Once the calibration operation is complete the receiver will issue a UBX message to indicate that the SMGR is reverting to normal operation and to report the results of the calibration. A default for the internal oscillator is available in the firmware.

Note that it is important that only the chosen frequency source is enabled during the calibration process and that it remains stable throughout the calibration period; otherwise incorrect oscillator measurements will be made and this will lead to miscalibration and poor subsequent operation of the receiver.

26.6 FTS device Output and Top Of Second (TOS) message

The outputs available from an FTS device can be one or all of the following:

- A disciplined frequency source at the same frequency as the internal oscillator.
- A 1PPS or an even second signal (other similar rates are possible) coherent with the internal oscillator, configured by UBX-CFG-TP5.
- Messages reporting measurement results (for example for a host disciplined external oscillator).
- A UBX-TIM-TOS message which describes the current condition (accuracy, coherent or non-coherent, etc...) of the frequency and PPS outputs.
- DAC command for disciplined external oscillators.

The top of second (TOS) message is a summary of the FTS device's status. It is output shortly after each time pulse and so will normally be aligned to the second of the reference time (if available). To guarantee that this message is output as the first message after the time pulse a system of time slot reservation is provided for all communication interfaces towards the host. For more information on this mechanism refer to the description of TX time slots

Users of the FTS variant are expected to use the UBX-TIM-TOS message to obtain key parameters for each time pulse. The UBX-TIM-TP message is only supported for compatibility with timing receivers and is not guaranteed to provide the most appropriate information in all FTS use cases.

The time pulse of an FTS device is generated differently from that of other u-blox receivers.

FTS products support two modes of time pulse generation: "coherent" and "non-coherent" pulses. "Coherent" pulse generation means that the number of clock cycles between two pulses is always the same. When in "non-coherent" pulse mode the receiver may change the number of clock cycles between two pulses if it can thus reduce the phase error of the time pulse. The receiver can be configured (using UBX-CFG-SMGR) to operate in either of these modes or to switch from "non-coherent" to coherent mode after initial frequency and phase error has been eliminated.

It can be useful to instruct the receiver to enter the "non-coherent" pulse mode during startup or while recovering from holdover; it reduces the time necessary for phase convergence. After the phase error is reduced the host can instruct the FTS receiver to switch back to "coherent" mode again.

The UBX-TIM-TOS message, when enabled, indicates the actual mode of pulse generation.

Depending on the time pulse generation mode, the time pulse can be forced to be phase aligned to the oscillators. In coherent output mode the phase offset of the oscillator at the rising edge of the time pulse is defined by the phaseOffset field of UBX-CFG-DOSC. In "non-coherent" mode this constraint is ignored.

The phase offset is handled differently for both oscillators. Whereas phase lock between the internal oscillator and the time pulse is guaranteed by hardware, in the case of the external oscillator the lock is achieved by software and that lock is therefore the lock behavior is expected to be different.

The frequency, shape and offset of the time pulse can be configured with the UBX-CFG-TP5 message. Some of the fields are interpreted differently by FTS devices compared to other u-blox receivers. Among others the lockGnssFreq flag is ignored and the time pulse is always aligned to the best synchronization source. Furthermore, switching between the two time pulse frequency and length parameters is not governed by GNSS alone but by the condition selected in the

syncMode field.

Two delay parameters can be configured using UBX-CFG-TP5, antCableDelay and userConfigDelay. In an FTS product care should be taken what delays are attributed to which of the delay terms. The antenna cable delay is only relevant when the receiver is following GNSS as reference; the user-configurable delay is applied regardless of the active reference signal.

In current FTS products only TIMEPULSE 2 can be used for pulse generation. Additionally, just 0.5 Hz, 1 Hz and 2 Hz time pulse output is supported by current FTS products. Other output frequencies may be configured with UBX-CFG-TP5 but are not guaranteed to work properly.

26.7 Message transmission time slot reservations on host interfaces

The firmware provides three message transmission time slots that are aligned to the time pulse output of the receiver. No message is scheduled for transmission in the first slot after the leading edge of the time pulse. The second slot is reserved for the UBX-TIM-TOS message and the third slot is used for outputting other messages. However, any message transmission that was started will be finished before a new message is started.

The time slots can be enabled and configured using UBX-CFG-TXSLOT.

When the reference time pulse is disabled or runs at a high frequency it may happen that many or all outgoing messages are lost. Therefore the time slot mechanism should be configured to match the time pulse behavior or disabled altogether.

This mechanism only controls when a message transmission may start and does not guarantee that the message transmission will finish before the end of the corresponding slot. Therefore the end of the last slot should be configured such that the longest enabled message can still be transmitted before the period starts when the receiver must not transmit messages.

The timing of the actual message output is also dependent on the communication interface and its clocking. On the slave interfaces (DDC and SPI) the host must provide clock in all time slots for this feature to work.

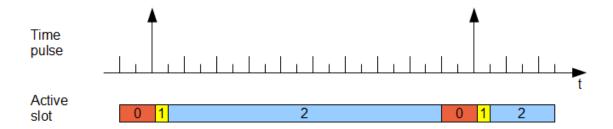

26.7.1 Example setup

Following is an example scenario. The receiver is set up to output a time pulse at a 1 Hz rate. Suppose that the following requirements are given for system integration:

- The TOS message should be output 10 to 50 ms after the time pulse.
- No other message should be output from the leading edge of the time pulse until 50 ms after the time pulse.
- The longest enabled message takes up to 100 ms to transmit through the chosen interface with the configured speed.

Then the time slots are enabled and the three slots are configured to end 10, 50 and 900 ms after the pulse respectively. The following figure indicates time pulses with upwards pointing arrows. Slot 0 (the first one active immediately after the time pulse) is active and thus blocks the transmission of new messages from 100 ms before the time pulse until 10 ms after it. Time slot 1, i.e. the time between 10 and 50 ms after the pulse, is reserved for the top-of-second message. All other messages are output in slot 2.

27 RTK Mode Configuration

This feature is only available with the High Precision GNSS products

u-blox RTK technology introduces the concept of a reference station and a rover. Using the RTCM3 protocol, the reference station sends corrections to the rover via a communication link enabling the rover to compute its position relative to the reference with high accuracy.

The reference station can provide correction to several rovers but the rover cannot concurrently process corrections from several reference stations.

The remainder of this chapter describes how to configure the reference station and the rover. More details about the RTCM3 protocol can be found in the RTCM3 section.

27.1 Reference Station Mode Configuration

Reference Station Mode is a special receiver mode where the receiver uses measurements from all available satellites to broadcast corrections. Configuring a stationary reference station is done in two steps:

- The receiver must be set in Time Mode using the configuration steps described in the Time Mode Configuration section.
- The RTCM3 correction stream must be configured following the rules detailed in the RTCM3 Configuration section. Each RTCM message must be individually enabled using UBX-CFG-MSG.

- The rover will need to have received both reference station observation messages and reference station position messages in order to attempt ambiguity fixes.
- When the reference station is in Time Mode, some error checking is performed on the entered, or surveyed-in, fixed position. If the result of these checks indicates that the fixed position may be incorrect, then a UBX-INF-WARNING message will be sent, with the text "Reference Station position seems incorrect".

27.2 Rover Mode Configuration

The RTK rover can be configured to work in either of these two differential modes using UBX-CFG-DGNSS:

- RTK fixed: In this mode, the rover will attempt to fix ambiguities whenever possible.
- RTK float: In this mode, the rover will estimate the ambiguities as float but will make no attempts at fixing them.

The time after which old RTCM data will be discarded can be specified using the dgnssTimeout field in UBX-CFG-NAV5.

By default the rover will begin operation in RTK fixed mode. Upon receiving an RTCM3 correction stream on any of its communication interfaces, the rover will parse the data, apply the correction and, if possible, fix ambiguities. In absence of correction data or if the correction data times out, the rover will operate in standard GNSS mode.

The time needed to resolve the ambiguity is affected by the baseline length as well as by multipath and satellite visibility at both rover and reference station.

27.3 Moving Baseline RTK Configuration

The moving baseline (MB) RTK mode differs from the standard RTK mode in that it does not require the reference to be stationary at a known location. In MB RTK mode, both the reference station and rover receivers can move while computing a centimeter-level accurate 3D vector between them. This is ideal for applications where the relative position offset between two moving vehicles is required such as, for example, the follow-me feature on a UAV.

For the sake of conciseness, in the moving baseline RTK context, the reference station and rover receivers are referred to as MB reference and MB rover, respectively.

27.3.1 MB Reference Configuration

Configuring a receiver to operate in MB reference mode is done in two steps:

- The receiver must be set in Time Mode disabled using the configuration message UBX-CFG-TMODE 3.
- The RTCM3 correction stream must be configured following the rules detailed in the RTCM3 Configuration section. Each RTCM message must be individually enabled using UBX-CFG-MSG.

If the MB reference moves, then its position changes over time. To ensure that the baseline is as accurate as possible:

- The MB reference position must be sent for each epoch the MB reference observations are sent.
- The MB reference and rover must use the same navigation update rate.

27.3.2 MB Rover Configuration

As in the standard RTK mode, it is possible to configure the MB rover to operate in RTK fixed or RTK float using the UBX-CFG-DGNSS message.

By default the MB rover will begin operation in RTK fixed mode.

As discussed in the Moving Baseline Expected Performance section, RTCM corrections can only be extrapolated over a few seconds when both reference and rover receivers are moving. Therefore, any dgnssTimeout value configured using the UBX-CFG-NAV5 message will be ignored by the MB rover.

27.3.3 Expected Performance

While the MB RTK solution aims at estimating the relative position with centimeter-level accuracy, the absolute position of each receiver is expected to be known with a standard GNSS accuracy of a few meters. Additionally, the performance of the MB RTK solution is limited by the following:

- A moving reference receiver typically experiences worse GNSS tracking than a static reference receiver in an open-sky environment and therefore the MB RTK performance may be degraded.
- The MB rover can only compute an optimal MB RTK solution if the time-matched RTCM observation and position messages are received within a predefined time limit. The MB rover will wait up to 700 ms for messages before falling back to an extrapolated MB RTK solution. The MB rover will extrapolate the MB reference observations and/or position for up to 3 s before falling back to standard GNSS operation.
- The achievable update rate of the MB RTK solution is limited by the communication link latency. As a rule of thumb, the communication link latency should be about half the desired navigation update period. If it exceeds 700 ms, the MB rover will not be able to compute an MB RTK solution, even at 1 Hz.
- Since the MB rover must wait for time-matched RTCM corrections from the MB RTK reference to compute its position, the overall latency of the MB RTK solution will be the sum of the communication link latency plus the MB RTK computation time.

When falling back to standard GNSS operation, the MB rover will automatically adjust the accuracy and status flag information contained in the messages listed in the RTCM3 Output section.

Upon recovering the RTCM correction stream, the MB rover will automatically try to revert to MB RTK operation.

28 Automotive Dead Reckoning (ADR)

This feature is only available with the ADR products.

28.1 Introduction

u-blox solutions for Automotive Dead Reckoning (ADR) allow high-accuracy positioning in places with poor or no GNSS coverage. ADR is based on Sensor Fusion Dead Reckoning (SFDR) technology, which combines GNSS measurements with those from external sensors.

ADR solutions use the messages of the External Sensor Fusion (ESF) class.

28.2 Solution Types

28.2.1 GAWT: Gyroscope, Accelerometer and Wheel Tick Solution

The GAWT solution combines data from wheel-tick sensors, accelerometers and gyroscopes to compute a fused navigation solution. There are several different possible GAWT variants, depending on which sensors are available. The minimum set of sensors required for computing **GAWT** solutions is:

- A speed/distance sensor providing a single wheel tick (sometimes called a speed tick) or speed measurement;
- A z-axis gyroscope measuring the vehicle yaw rate;

An x-axis accelerometer measuring the vehicle forward-backward acceleration.

The solution may be further improved by using the following additional sensors:

- A 3-axis accelerometer can improve the height estimation accuracy;
- If the z-axis gyroscope is not aligned to the vehicle vertical axis then a 3-axis gyroscope with IMU-mount misalignment configuration (UBX-CFG-ESFALG) will allow the receiver to re-create the output of a correctly aligned z-axis gyroscope. This will result in improved planimetric accuracy compared to a single mis-aligned z-axis gyroscope.
- A temperature sensor can be used to compensate for temperature-dependent gyroscope errors. Depending on the sensor specification and temperature variation, this can significantly improve performance during periods of dead reckoning (see Gyroscope Configuration section for more details).

To operate ADR products in GAWT mode, the following tasks need to be completed:

 Sensor configuration (only for chipset products): the Wheel-Tick/Speed Sensor, the Gyroscope and the Accelerometers settings must be set up, and the Sensor Time Tagging must be properly configured. If the sensors data are properly fed to the receiver and configuration is successful, the sensors should appear in the UBX-ESF-STATUS message.

The ADR module products (NEO-M8L), the receiver is ready to operate in ADR (GAWT) navigation mode (this note is only valid in protocol versions 15.01+).

• Installation configuration: the IMU-mount Misalignment should be accurately configured for the receiver to achieve fusion solution.

Once these steps are completed, the firmware is ready to be operated in ADR GAWT navigation mode.

28.3 Installation Configuration

If the GNSS antenna is placed at a significant distance from the receiver, position offsets can be introduced which might affect the accuracy of the navigation solution. In order to compensate for the position offset advanced configurations can be applied. Contact u-blox support for more information on advanced configurations.

28.3.1 IMU-mount Alignment

(This feature is not supported in protocol versions less than 15.01).

The default assumption is that the IMU-frame and the installation-frame have the same orientation (i.e. all axes are parallel). If this assumption is not valid, the positioning solution can be degraded if the IMU-mount misalignment angles are small (typically few degrees) or can even fail in case of large (tens of degrees) IMU-mount misalignments. Therefore, it is important to correctly configure the IMU-mount misalignment settings by using the UBX-CFG-ESFALG configuration message.

This section describes how IMU-mount misalignment angles, i.e. the angles which rotate the installation-frame to the IMU-frame, can be configured using the UBX-CFG-ESFALG configuration message (see User-defined Configuration section below).

If the IMU-mount misalignment angles are unknown, they can be estimated during a dedicated initialization drive through an automatic alignment procedure. This is described in the Automatic IMU-Mount Alignment section below.

🔭 In u-blox module products containing an internal IMU (e.g. NEO-M8U modules), the IMU-

mount misalignment angles are estimated automatically by default (see **Automatic IMU-Mount Alignment** section below for further details).

28.3.1.1 Definitions

The IMU-mount misalignment angles are defined as follows:

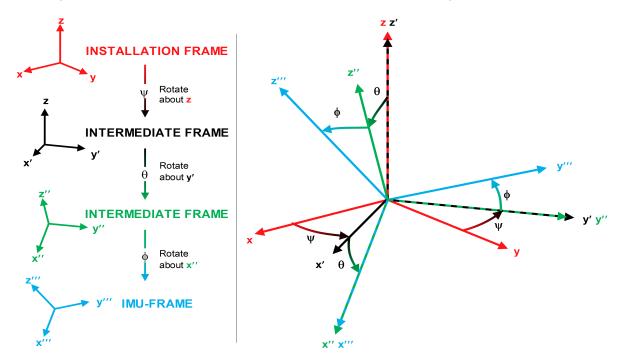

• The transformation from the installation-frame to the IMU-frame is described by three Euler angles about the installation-frame axes denoted as IMU-mount roll, IMU-mount pitch and IMU-mount yaw angles. All three angles are referred as the IMU-mount misalignment angles.

There is a single IMU-mount misalignment configuration that applies to both gyroscopes and accelerometers, so these sensors must be aligned with each other if both types are present.

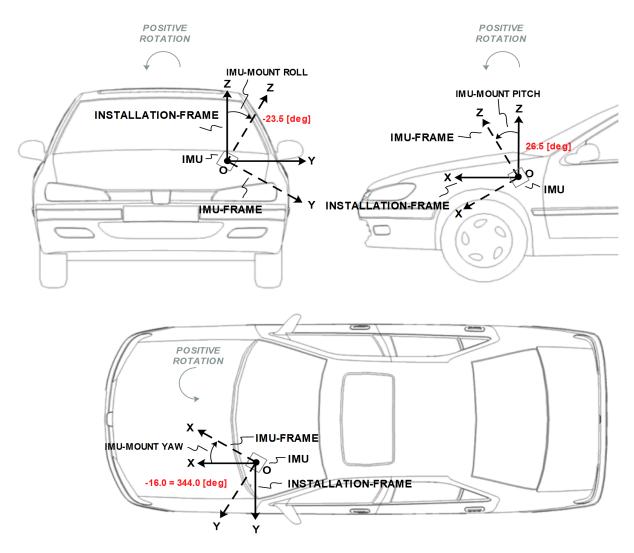

28.3.1.2 User-defined IMU-mount Alignment

The user can configure manually some IMU-mount roll, pitch and yaw angles using the UBX-CFG-ESFALG configuration message. The values that should be set in the configuration message are the Euler angles required to rotate the installation-frame to the IMU-frame. The IMU-mount yaw rotation should be performed first, then the IMU-mount pitch and finally the IMU-mount roll. At each stage, the rotation is around the appropriate axis of the transformed installation-frame, meaning that the order of the rotation sequence is important (see figure below).

If there is only a single IMU-mount misalignment angle then it may be measured as shown in the three examples below.

T

In order to prevent significant degradation of the positioning solution the IMU-mount misalignment angles should be configured with an accuracy of at least 5 degrees.

The list below describes in details how the fields in the UBX-CFG-ESFALG message must be interpreted with respect to example illustrated in the figure above:

- User-defined IMU-mount yaw angle: The IMU-mount yaw angle (yaw) corresponds to the rotation around the installation-frame z-axis (vertical) required for aligning the installation-frame to the IMU-frame (yaw = 344.0 deg if the IMU-mount misalignment is composed of a single rotation around the installation-frame z-axis, i.e. with no IMU-mount roll and IMU-mount pitch rotation).
- User-defined IMU-mount pitch angle: The IMU-mount pitch angle (pitch) corresponds to the rotation around the installation-frame y-axis required for aligning the installation-frame to the IMU-frame (pitch = 26.5 deg if the IMU-mount alignment is composed of a single rotation around the installation-frame y-axis, i.e. with no IMU-mount roll and IMU-mount yaw rotation).
- User-defined IMU-mount roll angle: The IMU-mount roll angle (roll) corresponds to the rotation around the installation-frame x-axis required for aligning the installation-frame to the IMU-frame (roll = -23.5 deg if the IMU-mount misalignment is composed of a single rotation around installation-frame x-axis, i.e. with no IMU-mount pitch and IMU-mount yaw rotation).

If automatic alignment is turned-on (see Automatic IMU-mount Alignment section), the angles obtained by polling UBX-CFG-ESFALG are still the user-defined angles which do not correspond to the result of the automatic IMU-mount alignment engine as output in UBX-ESF-ALG (see IMU-mount Misalignment Angles Output section for more details).

28.3.1.3 Automatic IMU-mount Alignment

The automatic IMU-mount alignment engine estimates automatically the IMU-mount roll, pitch and yaw angles. It requires an initialization phase during which no INS/GNSS fusion can be achieved (see Filter Modes section for further details). The progress of the automatic alignment initialization can be monitored with the UBX-ESF-STATUS message, and/or with the UBX-ESF-ALG message providing more details. When the vehicle is subject to sufficient dynamics (i.e. left and right turns during a normal drive), the automatic IMU-mount alignment engine will estimate the IMU-mount misalignment angles which have the same meaning as defined in the Definitions section, regardless whether the user did or not enter manually some IMU-mount misalignment angles (see User-defined Configuration section). Once the automatic IMU-mount alignment engine has sufficient confidence in the estimated initial IMU-mount misalignment angles, the IMU-mount misalignment angles initialization phase is completed. The raw accelerometer and gyroscope data (i.e. the IMU observations) are then compensated for IMU-mount misalignment and sensor fusion can be done. The resulting IMU-mount misalignment angles are output in the UBX-ESF-ALG message.

For automatic IMU-mount alignemnt a 3-axis gyroscope and 3-axis accelerometer is required (only valid in protocol versions 19.2+).

28.3.1.3.1 Enabling/Disabling Automatic IMU-mount Alignment

The user can activate/deactivate the automatic IMU-mount alignment by setting the doAutoMntAlg bit in the UBX-CFG-ESFALG configuration message.

If automatic IMU-mount alignment is deactivated while aligning, the estimated misalignment angles that were available at deactivation time are used (only if they were initialized, see next section). If automatic IMU-mount alignment is re-activated, alignment is pursued by starting from the state where deactivation happened (only valid in protocol versions 19+).

28.3.1.4 Limitation with Single-Axis Gyroscope

Gyroscope-mount misalignment is only supported when a three-axis gyroscope is available. In case of a single-axis gyroscope, the sensor should be physically aligned along the installation-frame z-axis. This is needed to avoid a scale factor error which will affect the accuracy of the output due to the two missing gyroscopes.

28.4 Sensor Configuration

This section describes the external sensor configuration parameters.

28.4.1 Accelerometer Configuration

The accelerometer sensor senses specific forces, expressed in meters per seconds squared, along its input axis. In the full configuration, an IMU contains a three-axis accelerometer whose sensitive axes are assumed to be mutually orthogonal in a Cartesian frame.

28.4.1.1 Messages

The accelerometer sensor can be configured in the following messages (only supported in protocol versions 15.01+):

Configuration Messages for ADR Products

| Product Type | Message | Solution Type |
|--------------|--------------|---------------------------------|
| Chipset | UBX-CFG-ESFA | UDR(only supported in protocol |
| | | versions 19.2+) |

28.4.2 Gyroscope Configuration

The gyroscope sensor senses angular rates, expressed in radians per seconds or degrees per second, along its input axis. In the full configuration, an IMU contains a three-axis gyroscope whose sensitive axes are assumed to be mutually orthogonal in a Cartesian frame.

28.4.2.1 Messages

The gyroscope sensor can be configured in the following messages (only supported in protocol versions 15.01+):

Configuration Messages for ADR Products

| Product Type | Message | Solution Type |
|--------------|--------------|---------------------------------|
| Chipset | UBX-CFG-ESFG | UDR(only supported in protocol |
| | | versions 19.2+) |

28.4.2.2 Temperature Compensation

Gyroscope sensors generally exhibit a temperature-dependent bias that varies from unit to unit. To help compensate for this variation the receiver builds up a table of gyroscope bias versus temperature measurements which are often available from the gyroscope sensor itself. This is particularly valuable to dead-reckoning-only navigation after the vehicle has been left for some time in parking garage.

The gyroscope temperature compensation engine has the following settings:

- Gyroscope RMS threshold above which temperature table is not updated: The gyroscope temperature-dependent bias is only updated if the measured gyroscope angular rate RMS is below the given threshold. This avoids artificially high estimates of the gyroscope temperature-dependent bias from transient events such as vehicle engine starts or nearby heavy construction. This threshold can be configured in the gyroRmsThdl field and is shared with the sensor accuracy estimation engine (see above);
- Temperature-dependent bias table saving rate: Gyroscope temperature compensation data are saved to non-volatile storage at intervals that can be configured by the tcTableSaveRate field.

The gyroscope temperature-dependent bias table is revised under the following conditions:

- The vehicle is stationary (without wheel-tick measurements or at zero speed);
- The RMS of the measured gyroscope angular rates and accelerometer specific forces is below a given threshold (see above);
- Turntable mode is not engaged (only for ADR products, see Ferry and Turntable Modes section);

Gyroscope temperature compensation is effective if the gyroscope(s) exhibits repeatable characteristics with temperature and is not unduly affected by external

factors (such as supply voltage or mechanical stress).

28.4.3 Wheel-Tick/Speed Sensor Configuration

28.4.3.1 Messages

The wheel-tick sensor can be configured in the following messages:

Configuration Messages for ADR Products

| Product Type | Message | Solution Type |
|-----------------------|---------------|---------------|
| Module (e.g. NEO-M8L) | UBX-CFG-ESFWT | GAWT |

28.4.3.2 Sensor Types

u-blox products support sensors delivering the following types of data:

- Relative wheel-tick data: If the wheel-tick sensor delivers relative wheel-tick counts (i.e. wheel-tick count since the previous measurement), the wtCountMax value must be set to 0.
- Absolute wheel-tick data: If the wheel-tick sensor delivers absolute wheel-tick counts (i.e.
 wheel-tick count since startup at time tag 0) that always increase, regardless of driving forward
 or backward (driving direction is indicated separately, see the ESF Measurement Data section),
 the wtCountMax value must be set to any non-zero value.
- By default, the maximum absolute wheel-tick counter value is automatically estimated by the receiver for a maximum counter value that can be represented as a 2^N value. Other maximum counter values must be manually configured. For example, a wtCountMax=1024 roll-over value would be automatically estimated, but a wtCountMax=1 000 must be configured. The maximum counter value is configured by setting the autoWtCountMaxOff bit and setting the wtCountMax value to the upper threshold of the absolute wheel-tick sensor count before starting again from zero (roll-over). (This note is only valid in protocol versions 19+).
 - If absolute wheel-tick data are used, the upper threshold towards which the absolute wheel-tick sensor counts ticks before starting again from zero (roll-over) must be configured in the wtCountMax field (This note is only valid in protocol versions less than 19).
- Speed data: The sensor delivers speed data in meters per second (data type 11 in ESF-MEAS).

 Data coming from this sensor type can only be delivered to the receiver via serial port (software interface).
- If speed data but no absolute or relative wheel-tick data are detected, the receiver automatically uses the speed data without the need of reconfiguring the useWtSpeed bit. This behaviour can be deactivated by setting the autoUseWtSpeedOff bit and by manually setting or clearing the useWtSpeed bit. If wheel-tick data (or both wheel-tick and speed data) are detected on the software interface, the receiver uses the data type (by default wheel-tick data) corresponding to the configured useWtSpeed bit value (This note is only valid in protocol versions 19+).
- To make the receiver interpret incoming speed data (data type 11 in ESF-MEAS) instead of the single wheel-tick data (data type 10 in ESF-MEAS) on the software interface, the useWtSpeed bit must be set (This note is only valid in protocol versions less than 19).
- It is strongly recommended to use absolute wheel-tick sensors in order to ensure robust measurement processing even after sensor failures or outages.

28.4.3.3 Interface

Wheel-tick/speed data can be delivered to u-blox products via the following interfaces:

• Hardware interface: Some u-blox products (e.g. NEO-M8L modules) have a pin dedicated to analog wheel-tick signal input and a pin dedicated to the wheel-tick direction signal. The receiver checks for analog wheel-tick signal input and will use it if the pin is correctly connected, the useWtPin flag is set (this is the default configuration for products having a pin dedicated to analog wheel-tick signal input), and the analog direction pin polarity is configured.

The analog direction signal polarity is automatically detected by the receiver. To manually configure the polarity, automatic detection must be turned-off by setting the autoDirPinPolOff bit and the polarity must be defined in the dirPinPol field (This note is only valid in protocol versions 19+).

The analog direction signal polarity must be configured in the dirPinPol field (This note is only valid in protocol versions less than 19).

Double edge counting can be enabled via the cntBothEdges flag. It can increase performance with low resolution wheel ticks. It does not fit all kinds of wheel tick signals. It must not be used with signals that are not generated with approximately 50% duty signal as it would worsen performance.

• Software interface: The sensor data are delivered to the receiver on the serial port (software interface) in the form of UBX-ESF-MEAS messages. Serial port can be configured for UART using the UBX-CFG-PRT message. For products with a hardware interface for analog wheel-tick signal input (e.g. NEO-M8L modules), the useWtPin bit must not be set if sensor data delivered via serial port should be used (only in protocol versions less than 19).

By default, the receiver automatically switches-off the hardware interface (i.e. ignores the useWtPin flag) if wheel-tick/speed data are detected on the software interface. Therefore data coming from the software interface will be prioritized over data coming from the hardware interface. To disable the automatic use of data detected on the software interface, the autoSoftwareWtOff bit must be set (This note is only valid in protocol versions 19+).

28.4.3.4 Settings

The following sensor settings can be configured:

- Sampling Frequency: The wheel-tick/speed data sampling frequency (wtFrequency) should be provided with an accuracy of about 10%. If not provided, it is automatically determined during initialization phase: this requires a consistent data rate and can take several minutes. Once initialized, the sampling frequency will be stored in non-volatile storage. For optimal navigation performance, the standard wheel-tick/speed input at 10 [Hz] is recommended.
- Accuracy: The wheel-tick/speed data accuracy (wtAccuracy) is defined as the standard deviation under normal operating conditions. Wheel-tick/speed data are corrupted by noise from sources inherent to the sensor. The accuracy is automatically determined and will then be stored in non-volatile storage.
- Latency: For best positioning performance, the latency of the wheel-tick/speed data (wtLatenc y) should be given as accurately as possible (to within at least 10 ms). If not provided, the wheeltick/speed data latency is assumed zero. More details about latency can be found in the Sensor Time Tagging section.
- Quantization error: If absolute/relative wheel-tick data are used and the tick data do not contain

raw tick counts (e.g. if the tick data is a distance), the quantization error can be defined in the wtQuantError or quantError fields. The quantization error can be calculated as 2*Pi*R / T with R the wheel radius, T the number of ticks per wheel rotation. If the quantization error is not provided, it is automatically initialized by the receiver.

- Sensor dead band: Some wheel-tick or speed sensors have a dead band which is the value below which no speed is reported. If this is the case, the value needs to be configured in the speedDeadBand field. However, the performance will still be degraded compared to having no dead band. If not provided, the receiver assumes the sensor has no dead band.
- Speed data accuracy: If speed data are used, the speed data accuracy can be set in the wtQuantError or quantError field. If not provided, the speed data accuracy is automatically initialized by the receiver.
- Scale factors: If the coarse scale factors are not configured by the user (wtFactor, factorR, factorF), they are estimated automatically during initialization (see Initialization Mode section for more details).
- Combination of multiple rear wheel-ticks: The receiver can be configured to use the combined rear wheel-ticks rather than the single-tick. It is recommended to use combined rear wheel-ticks if available, as they are often of higher quality than the single-ticks. If DWT, GWT and GAWT solutions are configured concurrently, combineTicks must be set to provide a consistent configuration. If combineTicks is set, the wheel-ticks basis settings (maximum value of the wheel-ticks counter, wheel-ticks sensor frequency, scale factors and quantization error) must reflect the properties of the rear wheel-ticks.

28.4.4 Sensor Time Tagging

In order to achieve optimal performance with the fusion solution it is essential to determine the epoch in the receiver time frame when the external sensor measurements were generated. This may be done in one of the following ways:

- First Byte Reception: reception time of first byte of UBX-ESF-MEAS message
- Time Mark on External Input: reception time of time mark signal sent to external input

The latency of the sensor data is the time between when the sensor measurement was taken and the detection at the receiver of either the first byte of the UBX-ESF-MEAS message or the preprocessor's time mark, depending on the timing approach chosen. Increased latency reduces the navigation performance.

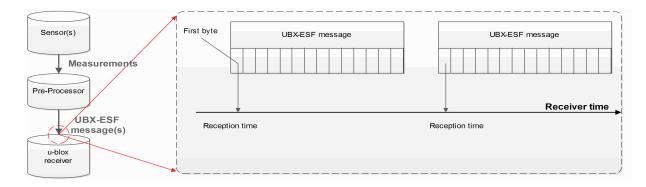

In ADR, the latency can be set by using the latency, wtLatency, gyroLatency and accelLatency parameters in the appropriate configuration message, as discussed in the Automotive Dead Reckoning (ADR) chapter.

In UDR, the latency can be set by using the latency parameter in the appropriate sensor configuration message, as discussed in the Untethered Dead Reckoning (UDR) chapter.

28.4.4.1 First Byte Reception

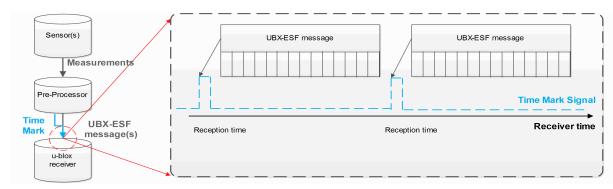

The easiest way to determine the sensor measurement generation time is to have the GNSS receiver assume the time of reception of the first byte of the UBX-ESF-MEAS message (minus a constant configured latency) to be the time of sensor measurement. This approach is the simplest to implement, but Time Mark on External Input can yield better latency control and compensation.

28.4.4.2 Time Mark on External Input

In this case, the preprocessor unit generating the measurements sends a signal to the EXTINT input of the GNSS receiver, marking the moment of measurement generation. The subsequent UBX-ESF-MEAS message is then flagged accordingly, and the measurements in the message will be assumed to have been generated at the time of external signal reception (minus a constant configured latency). This approach is the preferred solution, but it can be difficult to realize an exact analog time signal for the preprocessor unit.

28.4.4.3 Sensor Time Tagging Configuration

The receiver requires external sensor packets time tagged in seconds.

The external sensor time tagging for WT can be configured in the UBX-CFG-ESFWT (not supported in protocol versions less than 15.01).

The following sensor time tagging settings need to be specified:

- Sensor time tag scale factor to seconds: (timeTagFactor): This parameters converts the sensor time tags from their original time unit into the required seconds. For example if the IMU raw packets are time-tagged in milliseconds, the scale factor for converting one millisecond into one seconds is 0.001.
- Sensor time tag maximum value: (timeTagMax): External sensor time tags are encoded in different data types (signed/unsigned, varying number of bytes) which might vary across sensor types. For example if the IMU raw packet's time-tag field is encoded into an unsigned long integer (4 bytes), the maximum possible time-tag value is 4294967295 (0xFFFFFFFFin hexadecimal).

28.5 ADR System Configuration

28.5.1 Enabling/Disabling Fusion Filter

The ADR fusion filter can be turned off by means of the useAdr bit in the UBX-CFG-NAVX5 configuration message. If fusion is turned off, the receiver outputs a GNSS-only solution.

28.5.2 Recommended Configuration

For an optimum ADR navigation performance, the recommended general configuration is the following:

• Navigation Rate: the standard navigation solution update rate of 1 Hz (see UBX-CFG-RATE message) is recommended. The wheel tick quantization error is a limiting factor when using high frequency updates. This means that navigation rates higher than 1 Hz may result in lower position accuracies.

Reconsider the enabled messages and features (e.g logging) at higher navigation rates to meet CPU load, memory and interface bandwidth constraints (Valid in protocol versions 19.2).

28.6 Operation

This section describes how the ADR receiver operates.

28.6.1 Fusion Filter Modes

The fusion filter operates in different modes which are output in the UBX-ESF-STATUS message.

The table below summarizes the different fusion filter modes with the associated tasks the receiver is doing.

Fusion Modes

| Mode | Performed Tasks / Possible Causes | Published Fix |
|------------------|--|---------------|
| | | Туре |
| Initialization | Initialization of IMU | 3D-Fix |
| | Initialization of IMU-mount alignment | (GNSS) |
| | Initialization of INS (position, velocity, attitude) | |
| | Initialization of wheel-tick sensor (ADR only) | |
| | IMU sensor error (e.g. missing data) detected (only supported | |
| | in protocol versions 19.2+) | |
| Fusion | Fine-calibration of IMU-mount misalignment angles (not | GNSS/DR Fix |
| | supported in protocol versions less than 19) | |
| | Fine-calibration of IMU sensors | |
| | Fine-calibrating of wheel-tick factors (ADR only) | |
| | UDR mode under ADR / WT sensor error (e.g. missing data) | |
| | detected (ADR only)(only supported in protocol versions 19.2+) | |
| Suspended Fusion | Sensor error (e.g. missing data) detected (only supported in | 3D-Fix |
| | protocol versions less than 19.2) | (GNSS) |
| | Ferry detected (ADR only) | |
| Disabled Fusion | Fatal fusion filter error occurred | 3D-Fix |
| | Fusion filter turned-off by user | (GNSS) |

More details about each fusion mode are given in the following sections.

28.6.1.1 Initialization Mode

The purpose of the initialization phase is to estimate all unknown parameters which are required for achieving fusion. The initialization phase is triggered after a receiver cold start or a filter reset in case of fusion failure. The receiver is in initialization mode if the fusionMode field in the UBX-ESF-STATUS message is 0:INITIALIZING. In this case the required sensor calibration status (cal ibStatus) is flagged as 0: NOT CALIBRATED and the navigation solution output during initialization is based on GNSS solely.

The initialization phase comprises the following internal steps whose status is published in the initStatus field of the UBX-ESF-STATUS message:

- IMU initialization: Unknown crucial IMU parameters such as sensor sampling frequency are estimated during initialization. As long as all required IMU parameters are not initialized, the status of the IMU initialization (imuInitStatus) is flagged as 1:INITIALIZING in the UBX-ESF-STATUS message. Moreover, the required sensor calibration statuses (calibStatus) are flagged as 0:NOT CALIBRATED in the UBX-ESF-STATUS message. Note that if the user configured all required sensor settings, this step is skipped and IMU initialization is flagged as 2: INITIALIZED (not supported in protocol versions less than 19).
- IMU-mount alignment initialization: If automatic IMU-mount alignment is enabled (see the Automatic IMU-mount Alignment Configuration section), initial IMU-mount roll, IMU-mount pitch and IMU-mount yaw angles need to be estimated. For that, good GNSS signal reception as well as sufficient vehicle dynamics (i.e. a series of left and right turns during a normal drive) need to be at hand. As long as the IMU-mount alignment is not initialized, the status of the IMU-mount alignment (mntAlgStatus) is flagged as 1:INITIALIZING in the UBX-ESF-STATUS message. Once initialized, the IMU-mount alignment status is flagged as 2:INITIALIZED. If no IMU-mount alignment is required, the IMU-mount alignment is flagged as 0:OFF. A detailed description of the automatic IMU-mount alignment operation can be found in the Automatic IMU-mount Alignment Operation section (not supported in protocol versions less than 15.01).
- INS initialization: Before entering fusion mode, the initial vehicle position, velocity and especially attitude (vehicle roll, pitch heading angles) needs to be known with sufficient accuracy. This is achieved during INS initialization phase (which comprises an INS coarse alignment step) using GNSS. As long as the fusion filter isn't initialized, the status of the INS initialization (insInitSt atus) is flagged as 1:INITIALIZING in the UBX-ESF-STATUS message. Once initialized, the INS initialization is flagged as 2:INITIALIZED (not supported in protocol versions less than 15.01).
- This section is valid only for protocol versions less than 19.2
- Wheel-tick sensor initialization (ADR products only): Before entering fusion mode, some parameters like initial wheel-tick factors need to be estimated with sufficient accuracy. This is achieved during wheel-tick sensor initialization phase using GNSS. As long as the wheel-tick parameters are not initialized, the status of the wheel-tick initialization (wtInitStatus) is flagged as 1:INITIALIZING in the UBX-ESF-STATUS message. Once initialized, the wheel-tick sensor initialization is flagged as 2:INITIALIZED and the parameters are stored in non-volatile storage. If no wheel-tick data are required (in UDR products), the wheel-tick initialization is flagged as 0:OFF (only valid in protocol versions less than 19.2).
- This section is valid only for protocol versions 19.2+
- Wheel-tick sensor initialization (ADR products only): Solution enters fusion mode (fusionMode field in the UBX-ESF-STATUS message is on 1:FUSION), even when wheel-tick is not yet initialized, following a UDR mode approach. WT sensor parameters, like initial wheel-tick

factors, are estimated in parallel and are used once estimated with sufficient accuracy. As long as the wheel-tick parameters are not initialized, the status of the wheel-tick initialization (wtInitStatus) is flagged as 1:INITIALIZING in the UBX-ESF-STATUS message. Once initialized, the wheel-tick sensor initialization is flagged as 2:INITIALIZED, WT data are used by the filter and the parameters are stored in non-volatile storage. If no wheel-tick data are required (in UDR products), the wheel-tick initialization is flagged as 0:OFF (only valid in protocol versions 19.2+).

Beside the wheel-tick factors, other parameters like direction pin polarity are initialized if requested.

• Sensor error (e.g. missing data) detected: Sensor timeout of more than 500ms will trigger an INS re-initialization (not supported in protocol versions less than 19.2).

Note that initialization phase requires good GNSS signal conditions as well as periods during which vehicle is stationary and moving (including turns). Once all required initialization steps are achieved, fusion mode is triggered and the calibration phase begins.

28.6.1.2 Fusion Mode

Once initialization phase is achieved, the receiver enters navigation mode. The receiver is in fusion mode if the fusionMode field in the UBX-ESF-STATUS message is set on 1:FUSION. The fusion filter then starts to compute combined GNSS/dead-reckoning fixes (fused solutions) and to calibrate the sensors required for computing the fused navigation solution (used bit set). This is the case when the sensor calibration status (calibStatus) is flagged as 1:CALIBRATING. As soon as the calibration reaches a status where optimal fusion performance can be expected, the sensor calibration status is flagged as 2/3:CALIBRATED.

28.6.1.3 Suspended Fusion Mode

Sensor fusion can be temporarily suspended in cases where no fused solution should/can be computed. The receiver is in the temporarily disabled fusion mode if the fusionMode field in the UBX-ESF-STATUS message is set on 2:SUSPENDED. In this case, the receiver computes a GNSS-only solution.

Fusion is suspended if:

- One or several sensors deliver erroneous data or no data at all, the fusion is suspended during the sensor failure period. The receiver automatically recovers once the affected sensor(s) is/are back to normal operation (only supported in protocol versions less than 19.2).
- The vehicle is detected to be on a ferry where wheel-ticks do not detect any displacement (in ADR products only).

28.6.1.4 Disabled Fusion Mode

Sensor fusion can be permanently switched off in cases where recurrent fusion failures happen or user turned off manually fusion. The receiver is in the permanently disabled fusion mode if the fusionMode field in the UBX-ESF-STATUS message is set on 3:DISABLED. In such a case, the receiver computes a GNSS-only solution.

Fusion is permanently disabled in the following cases:

- If the fusion filter was manually turned off by the user (useAdr bit in the UBX-CFG-NAVX5 message is not set).
- If significantly wrong installation or filter parameters causing filter divergence are sent to the receiver

• If the fusion filter encountered too many errors.

An IMU-mount alignment error is output in the error field in the UBX-ESF-ALG message.

28.6.2 Accelerated Initialization and Calibration Procedure

This section describes how to perform fast initialization and calibration of the ADR receiver for the purpose of evaluation.

The duration of the initialization phase mostly depends on the quality of the GNSS signals and the dynamics encountered by the vehicle. Therefore the car should be driven to an open and flat area like an empty open-sky parking area for example. The initialization and calibration drive should contain phases where the car is stopped during a few minutes (with engine turned on), phases where the car is doing normal left and right turns and phases where speed is above 30 km/h under good GNSS reception conditions.

The initialization time required for reaching fused navigation mode can be shortened by following the procedure in the order described in the table below.

Accelerated Initialization Procedure

| Phase | Procedure | Indicator of Success |
|--------------------|--|---|
| IMU initialization | After receiver coldstart or first | IMU initialization status (imuInitStat |
| | receiver use, turn-on car engine and | us) is flagged as 2:INITIALIZED in the |
| | stay stationary under good GNSS | UBX-ESF-STATUS message. |
| | signal reception conditions during at | |
| | least 3 minutes. | |
| | This step can be skipped in DWT | |
| | navigation mode. | |
| INS initialization | Once IMU is initialized, stay | GNSS 3D fix achieved, good 3D position |
| (position and | stationary under good GNSS signal | accuracy (at least 5 m), high number of |
| velocity) | reception conditions until a reliable | used SVs (check UBX-NAV-PVT |
| | GNSS fix could be achieved. | message). |
| IMU-mount | Start driving with a minimum speed | IMU-mount alignment status (mntAlgS |
| alignment | of 30 km/h and do a series of | tatus) is flagged as 2: INITIALIZED in |
| initialization | approximately 10 left and right turns | the UBX-ESF-STATUS message, the |
| | (at least 90 degrees turns). Each | IMU-mount alignment status (status) |
| | turn should be completed as if the | is flagged as 3:COARSE ALIGNED in the |
| | vehicle would drive in a sharp | UBX-ESF-ALG message. |
| | roundabout. | |
| | This step can be skipped if | |
| | automatic IMU-mount alignment is | |
| | turned off. | |
| Wheel-tick sensor | Drive for at least 500 meters at a | Wheel-tick sensor initialization status (|
| initialization | minimum speed of 20 km/h. To | wtInitStatus) is flagged as 2: |
| | shorten this calibration step, the car | INITIALIZED in the UBX-ESF-STATUS |
| | should be driven at higher speed | message. |
| | (around 50 km/h) for at least 10 | |
| | seconds under good GNSS visibility. | |
| INS initialization | Drive straight for at least 100 | INS initialization status (insInitStatu |
| (attitude) | meters at a minimum speed of 40 | s) is flagged as 2:INITIALIZED in the |
| | km/h. | UBX-ESF-STATUS message. |

Once initialization is completed, the fusionMode field in the UBX-ESF-STATUS message switches to 1: FUSION, combined GNSS/dead-reckoning fixes (fused solutions) are output and the sensors used in the navigation filter start to get calibrated. Calibration is a continuous process running in the background and directly impacting the navigation solution quality.

The calibration time required for reaching optimal ADR navigation performance can be shortened by following the procedure described in the table below.

Accelerated Calibration Procedure

| Phase | Procedure | Indicator of Success |
|-----------------|--------------------------------------|-------------------------------------|
| IMU-mount | Keep driving with a minimum speed | Once the IMU-mount alignment engine |
| | | |
| alignment | of 30 km/h and do a series of left | has high confidence in its |
| calibration | and right turns (at least 90 degrees | misalignment angle estimates, the |
| | with similar sharpness as when | IMU-mount alignment status (status) |
| | driving in a sharp roundabout). At | is flagged as 4:FINE ALIGNED in the |
| | each turn the estimated IMU-mount | UBX-ESF-ALG message. |
| | misalignment angles are refined and | |
| | their accuracy increased. | |
| | This step can be skipped if | |
| | automatic IMU-mount alignment is | |
| | turned-off. | |
| IMU calibration | Drive curves and straight segments | The calibration status of the used |
| (gyroscope and | during a few minutes by including a | sensors (calibStatus) is flagged as |
| accelerometer) | few stops lasting at least 30 | 2/3:CALIBRATED in the UBX-ESF- |
| | seconds each. This drive should also | STATUS message. |
| | include some periods with higher | |
| | speed (at least 50 km/h) and can | |
| | typically be carried out on normal | |
| | open-sky roads with good GNSS | |
| | signal reception conditions. | |

Note that the calibration status (calibStatus in UBX-ESF-STATUS message) of some used sensors might fall back to 1:CALIBRATING if the receiver is operated in challenging conditions. In such a case, fused navigation solution uncertainty increases until optimal conditions are observed again for re-calibrating the sensors.

The fused navigation performance quality might also depend on how well the gyroscope temperature compensation table is populated. The table gradually fills in while the vehicle is stationary and by observing gyroscope biases at different temperatures. Therefore the quality of the gyroscope temperature compensation depends on how many temperature bins could be observed while the vehicle was stationary and on the duration of observation for each bin.

28.6.3 Automatic IMU-mount Alignment

(This feature is not supported in protocol versions less than 15.01).

28.6.3.1 Alignment Solution Output

The IMU-mount misalignment angles are output in the UBX-ESF-ALG message. They have the following meaning:

• IMU-mount yaw angle: During IMU-mount yaw angle initialization (status field is equal to 2),

the published angle (yaw) corresponds to the current estimated value but is not yet applied for rotating the IMU observations. After initialization (status field is equal or higher than 3), the published angle corresponds to the estimated value and is applied for rotating the IMU observations. If automatic IMU-mount alignment is disabled, the published angle corresponds to the IMU-mount yaw angle configured by the user (see User-defined Configuration section) and is applied for rotating the IMU observations.

- IMU-mount pitch angle: During IMU-mount pitch angle initialization (status field is equal to 1), the published angle (pitch) corresponds to the current estimated value but is not yet applied for rotating the IMU observations. After initialization (status field is equal or higher than 3), the published angle corresponds to the estimated value and is applied for rotating the IMU observations. If automatic IMU-mount alignment is disabled, the published angle corresponds to the IMU-mount pitch angle configured by the user (see User-defined Configuration section) and is applied for rotating the IMU observations.
- IMU-mount roll angle: During IMU-mount roll angle initialization (status field is equal to 1), the published angle (roll) corresponds to the current estimated value but is not yet applied for rotating the IMU observations. After initialization (status field is equal or higher than 3), the published angle corresponds to the estimated value and is applied for rotating the IMU observations. If automatic IMU-mount alignment is disabled, the published angle corresponds to the IMU-mount roll angle configured by the user (see User-defined Configuration section) and is applied for rotating the IMU observations.

If user-defined IMU-mount misalignment angles were configured by the user using UBX-CFG-ESFALG (see User-defined Configuration section) and automatic IMU-mount alignment is active, the angles output in the UBX-ESF-ALG message still correspond to the definition given above: they represent the full rotation required for transforming IMU data from installation-frame to IMU-frame. This means that the output misalignment angles are computed from the composed rotation of the user-defined rotation and the internally-estimated rotation.

28.6.3.2 Alignment Progress

The progress of the automatic IMU-mount alignment can be monitored by checking the status field in the UBX-ESF-ALG message (see the UBX-ESF-ALG message description for the meaning of the values output in the status field).

- IMU-mount roll/pitch angle initialization ongoing: The alignment engine is initializing the IMU-mount roll and pitch angles (status is 1). Both angles can only be initialized if vehicle encounters left and right turns (as occurring during a normal drive).
- **IMU-mount yaw angle initialization ongoing**: The alignment engine is initializing the IMU-mount yaw angle (status is 2). IMU-mount yaw angle can only be initialized once IMU-mount roll and pitch angles are initialized and if vehicle encounters left and right turns (as occurring during a normal drive).
- IMU-mount misalignment angles are initialized (only supported in protocol versions 15.01 to 17): The alignment engine has sufficient confidence in all IMU-mount misalignment angles and validates their use for compensating the accelerometer and gyroscope data, i.e. fused navigation solutions can be computed (status is 3).
- IMU-mount alignment coarse calibration ongoing (only supported in protocol versions 19+):
 Once initialized (status is 3), the automatic IMU-mount alignment engine has sufficient confidence in all IMU-mount misalignment angles and validates their use for compensating the

accelerometer and gyroscope data (fused navigation solutions can be computed). The engine keeps filtering the IMU-mount misalignment angles every time the observed vehicle dynamics allows for it.

• IMU-mount alignment fine calibration ongoing (only supported in protocol versions 19+): Once the IMU-mount misalignment angles are estimated with a good accuracy, the automatic IMU-mount alignment engine becomes more conservative in updating the IMU-mount misalignment angles (status is 4).

28.6.3.3 Alignment Errors

The following errors might be output in the error bitfield of the UBX-ESF-ALG message:

- IMU-mount misalignment angle error (only supported in protocol versions 15.01 to 17): If the automatic IMU-mount alignment engine suspects wrong IMU-mount misalignment angles (either due to a wrong initialization or a change in the physical mounting of the device), the error bit 0 in the UBX-ESF-ALG message is set.
- IMU-mount roll/pitch angle error (only supported in protocol versions 19+): If the automatic IMU-mount alignment engine suspects wrong IMU-mount roll and/or IMU-mount pitch misalignment angles (either due to a wrong initialization or a change in the physical mounting of the device), the error bit 0 in the UBX-ESF-ALG message is set.
- **IMU-mount yaw angle error** (only supported in protocol versions 19+): If the automatic IMU-mount alignment engine suspects wrong IMU-mount yaw misalignment angle (either due to a wrong initialization or a change in the physical mounting of the device), the error bit 1 in the UBX-ESF-ALG message is set.
- Euler Angle singularity ('gimbal-lock') error (only supported in protocol versions 19+): The Euler angle singularity error bit 2 is set when the automatic IMU-mount alignment engine detects an installation where the IMU-frame is misaligned in such a way that a degree of freedom is lost when two IMU-mount misalignment (Euler) angles begin to describe the same rotations (or axes). This happens for example with an IMU-mount misalignment of +/- 90 degrees around the IMU-mount pitch axis, where IMU-mount roll and IMU-mount yaw cannot be distinguished from each other. In such a case, these IMU-mount misalignment angles start to heavily fluctuate with time due to the mathematical singularity occurring at these points, meaning that the IMU-mount misalignment angles output in the UBX-ESF-ALG are not stable in time. Note however that each individual set of IMU-mount misalignment angles output in such a case still describes the correct rotation. Moreover, the internal rotation applied for aligning the IMU readings doesn't suffer from this singularity issue and optimal fusion can still be achieved.

28.6.4 Navigation Output

28.6.4.1 Local-level North-East-Down (NED) Frame

The local-level frame is a geodetic frame with following features:

- The origin (O) is a point on the Earth surface;
- The x-axis points to North;
- the y-axis points to East;
- the z-axis completes the right-handed reference system by pointing down.

The frame is referred to as North-East-Down (NED) since its axes are aligned with the North, East and Down directions.

28.6.4.2 Vehicle-Frame

The vehicle-frame is a right-handed 3D Cartesian frame rigidly connected with the vehicle and is used to determine the attitude of the vehicle with respect to the local-level frame. It has the following features:

- The origin (O) is the VRP in protocol versions less than 19.2, otherwise, is the origin of the IMU instrumental frame;
- The x-axis points towards the front of the vehicle;
- the y-axis points towards the right of the vehicle;
- the z-axis completes the right-handed reference system by pointing down.

28.6.4.3 Vehicle Position and Velocity Output

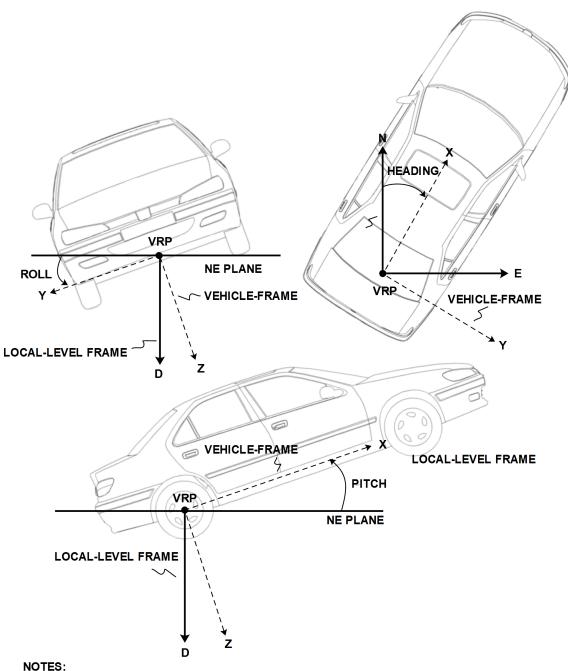

The position and velocity information is output in several messages like UBX-NAV-PVT for example. In protocol versions less than 19.2, position and velocity computed by the ADR navigation filter are referenced to the VRP. For protocol versions 19.2+, position and velocity are referenced to the origin of the IMU instrumental frame.

28.6.4.4 Vehicle Attitude Output

(Only supported in protocol versions 19+).

The transformation between the vehicle-frame and the local-level frame is described by three attitude angles about the local-level axes denoted as vehicle roll, vehicle pitch and vehicle heading. All three angles are referred as vehicle attitude and are illustrated in the figure below:

NOTES: N = NORTH, E = EAST, D = DOWN, IMU-FRAME ALIGNED WITH VEHICLE-FRAME

The order of the sequence of rotations around the navigation axes defining the vehicle attitude matrix in terms of vehicle attitude angles is illustrated below:

VEHICLE ATTITUDE DEFINITION

 ϕ : Vehicle roll angle

heta : Vehicle pitch angle

 ψ : Vehicle heading angle

 ${f C}_h^n$: Rotation between body-frame (b) and local-level NED navigation-frame (n)

$$\mathbf{C}_X = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos(\phi) & \sin(\phi) \\ 0 & -\sin(\phi) & \cos(\phi) \end{bmatrix} \quad \mathbf{C}_Y = \begin{bmatrix} \cos(\theta) & 0 & -\sin(\theta) \\ 0 & 1 & 0 \\ \sin(\theta) & 0 & \cos(\theta) \end{bmatrix} \quad \mathbf{C}_Z = \begin{bmatrix} \cos(\psi) & \sin(\psi) & 0 \\ -\sin(\psi) & \cos(\psi) & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

$$\begin{split} \mathbf{C}_b^n &= \mathbf{C}_Z^T \cdot \mathbf{C}_Y^T \cdot \mathbf{C}_X^T \\ &= \begin{bmatrix} \cos{(\theta)}\cos{(\psi)} & \sin{(\phi)}\sin{(\theta)}\cos{(\psi)} - \cos{(\phi)}\sin{(\psi)} & \cos{(\phi)}\sin{(\theta)}\cos{(\psi)} + \sin{(\phi)}\sin{(\psi)} \\ \cos{(\theta)}\sin{(\psi)} & \sin{(\phi)}\sin{(\phi)}\sin{(\psi)} + \cos{(\phi)}\cos{(\psi)} & \cos{(\phi)}\sin{(\theta)}\sin{(\psi)} - \sin{(\phi)}\cos{(\psi)} \\ -\sin{(\phi)} & \sin{(\phi)}\cos{(\theta)} & \cos{(\phi)}\cos{(\phi)} \end{bmatrix} \end{split}$$

Note that in this figure the body-frame corresponds to the vehicle-frame.

The vehicle attitude is output in the UBX-NAV-ATT message. The message provides all three angles together with their accuracy estimates.

Roll angle estimation only supported in protocol versions 19.2+.

28.6.4.5 Vehicle Dynamics Output

(Only supported in protocol versions 19+).

The UBX-ESF-INS message outputs information about vehicle dynamics provided by the INS: compensated vehicle angular rates and compensated vehicle accelerations. The acceleration data is free of any gravitational acceleration. Its accuracy is directly dependent on the filter attitude estimation accuracy.

Compensated vehicle dynamics information is output with respect to the vehicle-frame.

The message outputs only dynamics information that is directly compensated by the fusion filter. This implies that depending on the solution type and the sensor availability, dynamics along some axes of the vehicle-frame might not be available.

28.6.5 Sensor Data Types

The supported sensor data types are:

Definition of Data Types

| Туре | Description | Unit | Format of the 24 data bits |
|------|-----------------------------------|--------------|----------------------------|
| 0 | none, data field contains no data | | |
| 14 | reserved | | |
| 5 | z-axis gyroscope angular rate | deg/s *2^-12 | signed |

Definition of Data Types continued

| Туре | Description | Unit | Format of the 24 data bits |
|------|-------------------------------------|-------------------|----------------------------|
| 6 | front-left wheel ticks | | Bits 0-22: unsigned |
| | | | tick value. Bit 23: |
| | | | direction indicator |
| | | | (0=forward, |
| | | | 1=backward) |
| 7 | front-right wheel ticks | | Bits 0-22: unsigned |
| | | | tick value. Bit 23: |
| | | | direction indicator |

| 11 | speed | m/s * 1e-3 | signed |
| 12 | gyroscope temperature | deg Celsius * 1e- | signed |
| | | 2 | |
| 13 | y-axis gyroscope angular rate | deg/s *2^-12 | signed |
| 14 | x-axis gyroscope angular rate | deg/s *2^-12 | signed |
| 16 | x-axis accelerometer specific force | m/s^2 *2^-10 | signed |
| 17 | y-axis accelerometer specific force | m/s^2 *2^-10 | signed |
| 18 | z-axis accelerometer specific force | m/s^2 *2^-10 | signed |

28.6.6 Raw Sensor Data Output

(This feature is not supported in protocol versions less than 15.01).

Some u-blox module products contain inertial sensors (IMU) that are directly connected to the GNSS and cannot be directly accessed from outside the module. The UBX-ESF-RAW message can be used to access raw measurements of these sensors. A variable number of data fields may be used in a single message and these can contain different types of measurements. The type of each measurement is specified in the dataType field. The possible data types are x, y and z-axis measurements on gyroscope or accelerometer and gyroscope temperature measurements as described in the ESF Measurement Data section. One UBX-ESF-RAW message can contain multiple samples from the same sensor. The user can separate and order these using the time tags attached to each of the measurements.

The measurements are made at a fixed rate. The sampling rate or other sensor configuration options can not be changed.

To turn on this feature the UBX-ESF-RAW message must be enabled using UBX-CFG-MSG. If non-zero rate is selected the message will be output but the selected rate does not otherwise have an influence at the rate of the messages.

Turning on this feature does not disable sensor fusion in the receiver. To use an external fusion algorithm consider disabling the automotive dead reckoning mode using UBX-CFG-NAVX5.

28.6.7 Receiver Startup and Shutdown

Continuous dead reckoning is possible over receiver restarts if the following conditions are true:

- Non-volatile storage is available, or the save-on-shutdown feature (SOS) is used
- The vehicle is not moved while the receiver is off

During periods of external sensor data unavailability the receiver switches to GNSS-only navigation if the last sensor information indicated the vehicle was moving.

29 Untethered Dead Reckoning (UDR)

This feature is only available with the UDR products.

29.1 Introduction

u-blox solution for Untethered Dead Reckoning (UDR) allows improved navigation performance in places with GNSS-denied conditions as well as during short GNSS outages. UDR is based on Sensor Fusion Dead Reckoning (SFDR) technology, which integrates an Inertial Navigation System (INS) with GNSS measurements. The INS integrates angular rates and specific forces sensed by an Inertial Measurement Unit (IMU). The INS computes position, velocity and attitude changes and can, once initialized, provide accurate navigation information. However, an inertial-only navigation solution would degrade quickly with time due to the errors corrupting the IMU observations. The integration of the INS with GNSS measurements bounds these time-growing errors by calibrating the INS. The resulting integrated INS/GNSS filter, called fusion filter below, has the following advantages compared to standalone GNSS positioning:

- Improved navigation performance in GNSS-denied conditions: errors caused by multipath or weak signal conditions are mitigated though the aid brought by the IMU.
- Navigation solution during short GNSS-outages: the INS bridges short GNSS gaps which might be caused by tunnels or parking garages.

UDR solution uses the messages of the External Sensor Fusion (ESF) class.

29.2 Installation Configuration

(The features in this section are not supported in protocol versions less than 19).

29.2.1 IMU-mount Alignment

(This feature is not supported in protocol versions less than 15.01).

The default assumption is that the IMU-frame and the installation-frame have the same orientation (i.e. all axes are parallel). If this assumption is not valid, the positioning solution can be degraded if the IMU-mount misalignment angles are small (typically few degrees) or can even fail

in case of large (tens of degrees) IMU-mount misalignments. Therefore, it is important to correctly configure the IMU-mount misalignment settings by using the <code>UBX-CFG-ESFALG</code> configuration message.

This section describes how IMU-mount misalignment angles, i.e. the angles which rotate the installation-frame to the IMU-frame, can be configured using the UBX-CFG-ESFALG configuration message (see User-defined Configuration section below).

If the IMU-mount misalignment angles are unknown, they can be estimated during a dedicated initialization drive through an automatic alignment procedure. This is described in the Automatic IMU-Mount Alignment section below.

In u-blox module products containing an internal IMU (e.g. NEO-M8U modules), the IMU-mount misalignment angles are estimated automatically by default (see Automatic IMU-Mount Alignment section below for further details).

29.2.1.1 Definitions

The IMU-mount misalignment angles are defined as follows:

• The transformation from the installation-frame to the IMU-frame is described by three Euler angles about the installation-frame axes denoted as IMU-mount roll, IMU-mount pitch and IMU-mount yaw angles. All three angles are referred as the IMU-mount misalignment angles.

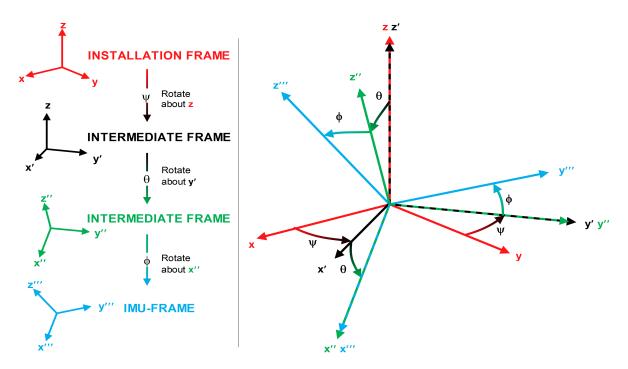

There is a single IMU-mount misalignment configuration that applies to both gyroscopes and accelerometers, so these sensors must be aligned with each other if both types are present.

29.2.1.2 User-defined IMU-mount Alignment

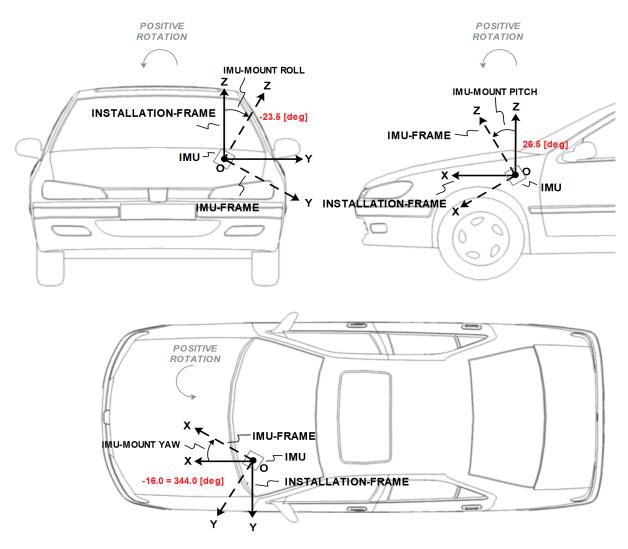

The user can configure manually some IMU-mount roll, pitch and yaw angles using the UBX-CFG-ESFALG configuration message. The values that should be set in the configuration message are the Euler angles required to rotate the installation-frame to the IMU-frame. The IMU-mount yaw rotation should be performed first, then the IMU-mount pitch and finally the IMU-mount roll. At each stage, the rotation is around the appropriate axis of the transformed installation-frame, meaning that the order of the rotation sequence is important (see figure below).

If there is only a single IMU-mount misalignment angle then it may be measured as shown in the three examples below.

 \Im

In order to prevent significant degradation of the positioning solution the IMU-mount misalignment angles should be configured with an accuracy of at least 5 degrees.

The list below describes in details how the fields in the UBX-CFG-ESFALG message must be interpreted with respect to example illustrated in the figure above:

- User-defined IMU-mount yaw angle: The IMU-mount yaw angle (yaw) corresponds to the rotation around the installation-frame z-axis (vertical) required for aligning the installation-frame to the IMU-frame (yaw = 344.0 deg if the IMU-mount misalignment is composed of a single rotation around the installation-frame z-axis, i.e. with no IMU-mount roll and IMU-mount pitch rotation).
- User-defined IMU-mount pitch angle: The IMU-mount pitch angle (pitch) corresponds to the rotation around the installation-frame y-axis required for aligning the installation-frame to the IMU-frame (pitch = 26.5 deg if the IMU-mount alignment is composed of a single rotation around the installation-frame y-axis, i.e. with no IMU-mount roll and IMU-mount yaw rotation).
- User-defined IMU-mount roll angle: The IMU-mount roll angle (roll) corresponds to the rotation around the installation-frame x-axis required for aligning the installation-frame to the IMU-frame (roll = -23.5 deg if the IMU-mount misalignment is composed of a single rotation around installation-frame x-axis, i.e. with no IMU-mount pitch and IMU-mount yaw rotation).

If automatic alignment is turned-on (see Automatic IMU-mount Alignment section), the angles obtained by polling UBX-CFG-ESFALG are still the user-defined angles which do not correspond to the result of the automatic IMU-mount alignment engine as output in UBX-ESF-ALG (see IMU-mount Misalignment Angles Output section for more details).

29.2.1.3 Automatic IMU-mount Alignment

The automatic IMU-mount alignment engine estimates automatically the IMU-mount roll, pitch and yaw angles. It requires an initialization phase during which no INS/GNSS fusion can be achieved (see Filter Modes section for further details). The progress of the automatic alignment initialization can be monitored with the UBX-ESF-STATUS message, and/or with the UBX-ESF-ALG message providing more details. When the vehicle is subject to sufficient dynamics (i.e. left and right turns during a normal drive), the automatic IMU-mount alignment engine will estimate the IMU-mount misalignment angles which have the same meaning as defined in the Definitions section, regardless whether the user did or not enter manually some IMU-mount misalignment angles (see User-defined Configuration section). Once the automatic IMU-mount alignment engine has sufficient confidence in the estimated initial IMU-mount misalignment angles, the IMU-mount misalignment angles initialization phase is completed. The raw accelerometer and gyroscope data (i.e. the IMU observations) are then compensated for IMU-mount misalignment and sensor fusion can be done. The resulting IMU-mount misalignment angles are output in the UBX-ESF-ALG message.

For automatic IMU-mount alignemnt a 3-axis gyroscope and 3-axis accelerometer is required (only valid in protocol versions 19.2+).

29.2.1.3.1 Enabling/Disabling Automatic IMU-mount Alignment

The user can activate/deactivate the automatic IMU-mount alignment by setting the doAutoMntAlg bit in the UBX-CFG-ESFALG configuration message.

If automatic IMU-mount alignment is deactivated while aligning, the estimated misalignment angles that were available at deactivation time are used (only if they were initialized, see next section). If automatic IMU-mount alignment is re-activated, alignment is pursued by starting from the state where deactivation happened (only valid in protocol versions 19+).

29.2.1.4 Limitation with Single-Axis Gyroscope

Gyroscope-mount misalignment is only supported when a three-axis gyroscope is available. In case of a single-axis gyroscope, the sensor should be physically aligned along the installation-frame z-axis. This is needed to avoid a scale factor error which will affect the accuracy of the output due to the two missing gyroscopes.

29.3 Sensor Configuration

This section describes the external sensor configuration parameters.

29.3.1 Accelerometer Configuration

The accelerometer sensor senses specific forces, expressed in meters per seconds squared, along its input axis. In the full configuration, an IMU contains a three-axis accelerometer whose sensitive axes are assumed to be mutually orthogonal in a Cartesian frame.

29.3.1.1 Messages

The accelerometer sensor can be configured in the following message:

Configuration Messages for UDR Products

| Product Type | Message |
|--------------|--------------|
| Chipset | UBX-CFG-ESFA |

29.3.2 Gyroscope Configuration

The gyroscope sensor senses angular rates, expressed in radians per seconds or degrees per second, along its input axis. In the full configuration, an IMU contains a three-axis gyroscope whose sensitive axes are assumed to be mutually orthogonal in a Cartesian frame.

29.3.2.1 Messages

The gyroscope sensor can be configured in the following message:

Configuration Messages for UDR Products

| Product Type | Message |
|--------------|--------------|
| Chipset | UBX-CFG-ESFG |

29.3.2.2 Temperature Compensation

Gyroscope sensors generally exhibit a temperature-dependent bias that varies from unit to unit. To help compensate for this variation the receiver builds up a table of gyroscope bias versus temperature measurements which are often available from the gyroscope sensor itself. This is particularly valuable to dead-reckoning-only navigation after the vehicle has been left for some time in parking garage.

The gyroscope temperature compensation engine has the following settings:

- Gyroscope RMS threshold above which temperature table is not updated: The gyroscope temperature-dependent bias is only updated if the measured gyroscope angular rate RMS is below the given threshold. This avoids artificially high estimates of the gyroscope temperature-dependent bias from transient events such as vehicle engine starts or nearby heavy construction. This threshold can be configured in the gyroRmsThdl field and is shared with the sensor accuracy estimation engine (see above);
- Temperature-dependent bias table saving rate: Gyroscope temperature compensation data are saved to non-volatile storage at intervals that can be configured by the tcTableSaveRate field.

The gyroscope temperature-dependent bias table is revised under the following conditions:

- The vehicle is stationary (without wheel-tick measurements or at zero speed);
- The RMS of the measured gyroscope angular rates and accelerometer specific forces is below a given threshold (see above);
- Turntable mode is not engaged (only for ADR products, see Ferry and Turntable Modes section);

Gyroscope temperature compensation is effective if the gyroscope(s) exhibits repeatable characteristics with temperature and is not unduly affected by external factors (such as supply voltage or mechanical stress).

29.3.3 Sensor Time Tagging

In order to achieve optimal performance with the fusion solution it is essential to determine the epoch in the receiver time frame when the external sensor measurements were generated. This may be done in one of the following ways:

- First Byte Reception: reception time of first byte of UBX-ESF-MEAS message
- Time Mark on External Input: reception time of time mark signal sent to external input

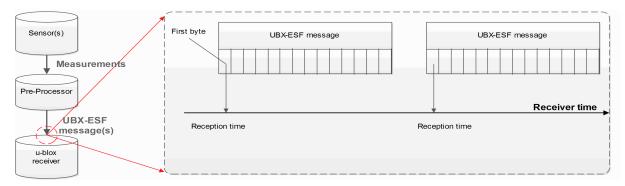

The latency of the sensor data is the time between when the sensor measurement was taken and the detection at the receiver of either the first byte of the UBX-ESF-MEAS message or the preprocessor's time mark, depending on the timing approach chosen. Increased latency reduces the navigation performance.

In ADR, the latency can be set by using the latency, wtLatency, gyroLatency and accelLatency parameters in the appropriate configuration message, as discussed in the Automotive Dead Reckoning (ADR) chapter.

In UDR, the latency can be set by using the latency parameter in the appropriate sensor configuration message, as discussed in the Untethered Dead Reckoning (UDR) chapter.

29.3.3.1 First Byte Reception

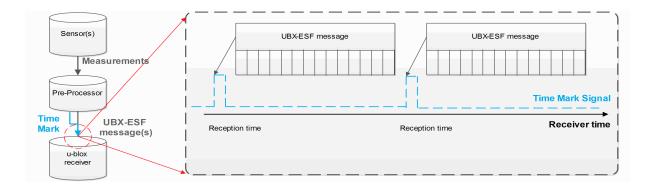

The easiest way to determine the sensor measurement generation time is to have the GNSS receiver assume the time of reception of the first byte of the UBX-ESF-MEAS message (minus a constant configured latency) to be the time of sensor measurement. This approach is the simplest to implement, but Time Mark on External Input can yield better latency control and compensation.

29.3.3.2 Time Mark on External Input

In this case, the preprocessor unit generating the measurements sends a signal to the EXTINT input of the GNSS receiver, marking the moment of measurement generation. The subsequent UBX-ESF-MEAS message is then flagged accordingly, and the measurements in the message will be assumed to have been generated at the time of external signal reception (minus a constant configured latency). This approach is the preferred solution, but it can be difficult to realize an exact analog time signal for the preprocessor unit.

29.3.3.3 Sensor Time Tagging Configuration

The receiver requires external sensor packets time tagged in seconds.

The external sensor time tagging for WT can be configured in the UBX-CFG-ESFWT (not supported in protocol versions less than 15.01).

The following sensor time tagging settings need to be specified:

- Sensor time tag scale factor to seconds: (timeTagFactor): This parameters converts the sensor time tags from their original time unit into the required seconds. For example if the IMU raw packets are time-tagged in milliseconds, the scale factor for converting one millisecond into one seconds is 0.001.
- Sensor time tag maximum value: (timeTagMax): External sensor time tags are encoded in different data types (signed/unsigned, varying number of bytes) which might vary across sensor types. For example if the IMU raw packet's time-tag field is encoded into an unsigned long integer (4 bytes), the maximum possible time-tag value is 4294967295 (0xFFFFFFFFin hexadecimal).

29.4 UDR System Configuration

(These features are not supported in protocol versions less than 19).

29.4.1 Enabling/Disabling Fusion Filter

The UDR fusion filter can be turned off by means of the useAdr bit in the UBX-CFG-NAVX5 configuration message. If fusion is turned off, the receiver outputs a GNSS-only solution.

29.4.2 Recommended Configuration

For an optimum navigation performance, the recommended general configuration is the following:

• Navigation Rate: the standard navigation solution update rate of 1 Hz (see UBX-CFG-RATE message) is recommended.

Reconsider the enabled messages and features (e.g logging) at higher navigation rates to meet CPU load, memory and interface bandwidth constraints (Valid in protocol versions 19.2).

29.5 Operation

This section describes how the UDR receiver operates.

29.5.1 Fusion Filter Modes

The fusion filter operates in different modes which are output in the UBX-ESF-STATUS message. The table below summarizes the different fusion filter modes with the associated tasks the

Fusion Modes

receiver is doing.

| Mode | Performed Tasks / Possible Causes | Published Fix |
|------------------|--|---------------|
| | | Туре |
| Initialization | Initialization of IMU | 3D-Fix |
| | Initialization of IMU-mount alignment | (GNSS) |
| | Initialization of INS (position, velocity, attitude) | |
| | Initialization of wheel-tick sensor (ADR only) | |
| | IMU sensor error (e.g. missing data) detected (only supported | |
| | in protocol versions 19.2+) | |
| Fusion | Fine-calibration of IMU-mount misalignment angles (not | GNSS/DR Fix |
| | supported in protocol versions less than 19) | |
| | Fine-calibration of IMU sensors | |
| | Fine-calibrating of wheel-tick factors (ADR only) | |
| | UDR mode under ADR / WT sensor error (e.g. missing data) | |
| | detected (ADR only)(only supported in protocol versions 19.2+) | |
| Suspended Fusion | Sensor error (e.g. missing data) detected (only supported in | 3D-Fix |
| | protocol versions less than 19.2) | (GNSS) |
| | Ferry detected (ADR only) | |
| Disabled Fusion | Fatal fusion filter error occurred | 3D-Fix |
| | Fusion filter turned-off by user | (GNSS) |

More details about each fusion mode are given in the following sections.

29.5.1.1 Initialization Mode

The purpose of the initialization phase is to estimate all unknown parameters which are required for achieving fusion. The initialization phase is triggered after a receiver cold start or a filter reset in case of fusion failure. The receiver is in initialization mode if the fusionMode field in the UBX-ESF-STATUS message is 0:INITIALIZING. In this case the required sensor calibration status (cal ibStatus) is flagged as 0: NOT CALIBRATED and the navigation solution output during initialization is based on GNSS solely.

The initialization phase comprises the following internal steps whose status is published in the initStatus field of the UBX-ESF-STATUS message:

- IMU initialization: Unknown crucial IMU parameters such as sensor sampling frequency are estimated during initialization. As long as all required IMU parameters are not initialized, the status of the IMU initialization (imuInitStatus) is flagged as 1: INITIALIZING in the UBX-ESF-STATUS message. Moreover, the required sensor calibration statuses (calibStatus) are flagged as 0:NOT CALIBRATED in the UBX-ESF-STATUS message. Note that if the user configured all required sensor settings, this step is skipped and IMU initialization is flagged as 2: INITIALIZED (not supported in protocol versions less than 19).
- IMU-mount alignment initialization: If automatic IMU-mount alignment is enabled (see the Automatic IMU-mount Alignment Configuration section), initial IMU-mount roll, IMU-mount pitch and IMU-mount yaw angles need to be estimated. For that, good GNSS signal reception as

well as sufficient vehicle dynamics (i.e. a series of left and right turns during a normal drive) need to be at hand. As long as the IMU-mount alignment is not initialized, the status of the IMU-mount alignment (mntAlgStatus) is flagged as 1:INITIALIZING in the UBX-ESF-STATUS message. Once initialized, the IMU-mount alignment status is flagged as 2:INITIALIZED. If no IMU-mount alignment is required, the IMU-mount alignment is flagged as 0:OFF. A detailed description of the automatic IMU-mount alignment operation can be found in the Automatic IMU-mount Alignment Operation section (not supported in protocol versions less than 15.01).

- INS initialization: Before entering fusion mode, the initial vehicle position, velocity and especially attitude (vehicle roll, pitch heading angles) needs to be known with sufficient accuracy. This is achieved during INS initialization phase (which comprises an INS coarse alignment step) using GNSS. As long as the fusion filter isn't initialized, the status of the INS initialization (insInitSt atus) is flagged as 1:INITIALIZING in the UBX-ESF-STATUS message. Once initialized, the INS initialization is flagged as 2:INITIALIZED (not supported in protocol versions less than 15.01).
- This section is valid only for protocol versions less than 19.2
- Wheel-tick sensor initialization (ADR products only): Before entering fusion mode, some parameters like initial wheel-tick factors need to be estimated with sufficient accuracy. This is achieved during wheel-tick sensor initialization phase using GNSS. As long as the wheel-tick parameters are not initialized, the status of the wheel-tick initialization (wtInitStatus) is flagged as 1:INITIALIZING in the UBX-ESF-STATUS message. Once initialized, the wheel-tick sensor initialization is flagged as 2:INITIALIZED and the parameters are stored in non-volatile storage. If no wheel-tick data are required (in UDR products), the wheel-tick initialization is flagged as 0:OFF (only valid in protocol versions less than 19.2).
- This section is valid only for protocol versions 19.2+
- Wheel-tick sensor initialization (ADR products only): Solution enters fusion mode (fusionMode field in the UBX-ESF-STATUS message is on 1:FUSION), even when wheel-tick is not yet initialized, following a UDR mode approach. WT sensor parameters, like initial wheel-tick factors, are estimated in parallel and are used once estimated with sufficient accuracy. As long as the wheel-tick parameters are not initialized, the status of the wheel-tick initialization (wtInitStatus) is flagged as 1:INITIALIZING in the UBX-ESF-STATUS message. Once initialized, the wheel-tick sensor initialization is flagged as 2:INITIALIZED, WT data are used by the filter and the parameters are stored in non-volatile storage. If no wheel-tick data are required (in UDR products), the wheel-tick initialization is flagged as 0:OFF (only valid in protocol versions 19.2+).
- Beside the wheel-tick factors, other parameters like direction pin polarity are initialized if requested.
- Sensor error (e.g. missing data) detected: Sensor timeout of more than 500ms will trigger an INS re-initialization (not supported in protocol versions less than 19.2).

Note that initialization phase requires good GNSS signal conditions as well as periods during which vehicle is stationary and moving (including turns). Once all required initialization steps are achieved, fusion mode is triggered and the calibration phase begins.

29.5.1.2 Fusion Mode

Once initialization phase is achieved, the receiver enters navigation mode. The receiver is in fusion mode if the fusionMode field in the UBX-ESF-STATUS message is set on 1: FUSION. The fusion filter then starts to compute combined GNSS/dead-reckoning fixes (fused solutions) and to calibrate the sensors required for computing the fused navigation solution (used bit set). This is

the case when the sensor calibration status (calibStatus) is flagged as 1:CALIBRATING. As soon as the calibration reaches a status where optimal fusion performance can be expected, the sensor calibration status is flagged as 2/3:CALIBRATED.

29.5.1.3 Suspended Fusion Mode

Sensor fusion can be temporarily suspended in cases where no fused solution should/can be computed. The receiver is in the temporarily disabled fusion mode if the fusionMode field in the UBX-ESF-STATUS message is set on 2: SUSPENDED. In this case, the receiver computes a GNSSonly solution.

Fusion is suspended if:

- · One or several sensors deliver erroneous data or no data at all, the fusion is suspended during the sensor failure period. The receiver automatically recovers once the affected sensor(s) is/are back to normal operation (only supported in protocol versions less than 19.2).
- The vehicle is detected to be on a ferry where wheel-ticks do not detect any displacement (in ADR products only).

29.5.1.4 Disabled Fusion Mode

Sensor fusion can be permanently switched off in cases where recurrent fusion failures happen or user turned off manually fusion. The receiver is in the permanently disabled fusion mode if the fusionMode field in the UBX-ESF-STATUS message is set on 3:DISABLED. In such a case, the receiver computes a GNSS-only solution.

Fusion is permanently disabled in the following cases:

- If the fusion filter was manually turned off by the user (useAdr bit in the UBX-CFG-NAVX5 message is not set).
- If significantly wrong installation or filter parameters causing filter divergence are sent to the receiver.
- If the fusion filter encountered too many errors.

An IMU-mount alignment error is output in the error field in the UBX-ESF-ALG message.

29.5.2 Accelerated Initialization and Calibration Procedure

This section describes how to perform fast initialization and calibration of the UDR receiver for the purpose of evaluation.

The duration of the initialization phase mostly depends on the quality of the GNSS signals and the dynamics encountered by the vehicle. Therefore the car should be driven to an open and flat area like an empty open-sky parking area for example. The initialization and calibration drive should contain phases where the car is stopped during a few minutes (with engine turned-on), phases where the car is doing normal left and right turns and phases where speed is above 30 km/h under good GNSS reception conditions.

The initialization time required for reaching fused navigation mode can be shortened by following the procedure in the order described in the table below.

Accelerated Initialization Procedure

| Thase Trocedure indicator of Success |
|--------------------------------------|
|--------------------------------------|

Accelerated Initialization Procedure continued

| Phase | Procedure | Indicator of Success |
|--------------------|---------------------------------------|---|
| IMU initialization | After receiver coldstart or first | IMU initialization status (imuInitStat |
| | receiver use, turn-on car engine and | us) is flagged as 2:INITIALIZED in the |
| | stay stationary under good GNSS | UBX-ESF-STATUS message. |
| | signal reception conditions during at | |
| | least 3 minutes. | |
| INS initialization | Once IMU is initialized, stay | GNSS 3D fix achieved, good 3D position |
| (position and | stationary under good GNSS signal | accuracy (at least 5 m), high number of |
| velocity) | reception conditions until a reliable | used SVs (check UBX-NAV-PVT |
| | GNSS fix could be achieved. | message). |
| IMU-mount | Start driving with a minimum speed | IMU-mount alignment status (mntAlgS |
| alignment | of 12 km/h and do a series of | tatus) is flagged as 2:INITIALIZED in |
| initialization | approximately 10 left and right turns | the UBX-ESF-STATUS message, the |
| | (at least 90 degrees turns). Each | IMU-mount alignment status (status) |
| | turn should be completed as if the | is flagged as 3:COARSE ALIGNED in the |
| | vehicle would drive in a sharp | UBX-ESF-ALG message. |
| | roundabout. | |
| | This step can be skipped if | |
| | automatic IMU-mount alignment is | |
| | turned-off. | |
| INS initialization | Drive straight for at least 100 | INS initialization status (insInitStatu |
| (attitude) | meters at a minimum speed of 40 | s) is flagged as 2:INITIALIZED in the |
| | km/h. | UBX-ESF-STATUS message. |

Once initialization is completed, the fusionMode field in the UBX-ESF-STATUS message switches to 1:FUSION, combined GNSS/Dead-reckoning fixes (fused solutions) are output and the sensors used in the navigation filter start to get calibrated. Calibration is a continuous process running in the background and improving the navigation solution quality.

The calibration time required for reaching optimal UDR navigation performance can be shortened by following the procedure described in the table below.

Accelerated Calibration Procedure

| Phase | Procedure | Indicator of Success |
|-------------|--------------------------------------|-------------------------------------|
| IMU-mount | Keep driving with a minimum speed | Once the IMU-mount alignment engine |
| alignment | of 30 km/h and do a series of left | has high confidence in its |
| calibration | and right turns (at least 90 degrees | misalignment angle estimates, the |
| | with similar sharpness as when | IMU-mount alignment status (status) |
| | driving in a sharp roundabout). At | is flagged as 4:FINE ALIGNED in the |
| | each turn the estimated IMU-mount | UBX-ESF-ALG message. |
| | misalignment angles are refined and | |
| | their accuracy increased. | |
| | This step can be skipped if | |
| | automatic IMU-mount alignment is | |
| | turned-off. | |

Accelerated Calibration Procedure continued

| Phase | Procedure | Indicator of Success |
|-----------------|--------------------------------------|-------------------------------------|
| IMU calibration | Drive curves and straight segments | The calibration status of the used |
| (gyroscope and | during a few minutes by including a | sensors (calibStatus) is flagged as |
| accelerometer) | few stops lasting at least 30 | 2/3:CALIBRATED in the UBX-ESF- |
| | seconds each. This drive should also | STATUS message. |
| | include some periods with higher | |
| | speed (at least 50 km/h) and can | |
| | typically be carried out on normal | |
| | open-sky roads with good GNSS | |
| | signal reception conditions. | |

Note that the calibration status (calibStatus in UBX-ESF-STATUS message) of some used sensors might fall back to 1:CALIBRATING if the receiver is operated in challenging conditions. In such a case, fused navigation solution uncertainty increases until optimal conditions are observed again for re-calibrating the sensors.

The fused navigation performance quality might also depend on how well the gyroscope temperature compensation table is populated. The table gradually fills in while the vehicle is stationary and by observing gyroscope biases at different temperatures. Therefore the quality of the gyroscope temperature compensation depends on how many temperature bins could be observed while the vehicle was stationary and on the duration of observation for each bin.

29.5.3 Automatic IMU-mount Alignment

(This feature is not supported in protocol versions less than 15.01).

29.5.3.1 Alignment Solution Output

The IMU-mount misalignment angles are output in the UBX-ESF-ALG message. They have the following meaning:

- IMU-mount yaw angle: During IMU-mount yaw angle initialization (status field is equal to 2), the published angle (yaw) corresponds to the current estimated value but is not yet applied for rotating the IMU observations. After initialization (status field is equal or higher than 3), the published angle corresponds to the estimated value and is applied for rotating the IMU observations. If automatic IMU-mount alignment is disabled, the published angle corresponds to the IMU-mount yaw angle configured by the user (see User-defined Configuration section) and is applied for rotating the IMU observations.
- IMU-mount pitch angle: During IMU-mount pitch angle initialization (status field is equal to 1), the published angle (pitch) corresponds to the current estimated value but is not yet applied for rotating the IMU observations. After initialization (status field is equal or higher than 3), the published angle corresponds to the estimated value and is applied for rotating the IMU observations. If automatic IMU-mount alignment is disabled, the published angle corresponds to the IMU-mount pitch angle configured by the user (see User-defined Configuration section) and is applied for rotating the IMU observations.
- IMU-mount roll angle: During IMU-mount roll angle initialization (status field is equal to 1), the published angle (roll) corresponds to the current estimated value but is not yet applied for rotating the IMU observations. After initialization (status field is equal or higher than 3), the published angle corresponds to the estimated value and is applied for rotating the IMU

observations. If automatic IMU-mount alignment is disabled, the published angle corresponds to the IMU-mount roll angle configured by the user (see User-defined Configuration section) and is applied for rotating the IMU observations.

If user-defined IMU-mount misalignment angles were configured by the user using UBX-CFG-ESFALG (see User-defined Configuration section) and automatic IMU-mount alignment is active, the angles output in the UBX-ESF-ALG message still correspond to the definition given above: they represent the full rotation required for transforming IMU data from installation-frame to IMU-frame. This means that the output misalignment angles are computed from the composed rotation of the user-defined rotation and the internally-estimated rotation.

29.5.3.2 Alignment Progress

The progress of the automatic IMU-mount alignment can be monitored by checking the status field in the UBX-ESF-ALG message (see the UBX-ESF-ALG message description for the meaning of the values output in the status field).

- IMU-mount roll/pitch angle initialization ongoing: The alignment engine is initializing the IMU-mount roll and pitch angles (status is 1). Both angles can only be initialized if vehicle encounters left and right turns (as occurring during a normal drive).
- **IMU-mount yaw angle initialization ongoing**: The alignment engine is initializing the IMU-mount yaw angle (status is 2). IMU-mount yaw angle can only be initialized once IMU-mount roll and pitch angles are initialized and if vehicle encounters left and right turns (as occurring during a normal drive).
- **IMU-mount misalignment angles are initialized** (only supported in protocol versions 15.01 to 17): The alignment engine has sufficient confidence in all IMU-mount misalignment angles and validates their use for compensating the accelerometer and gyroscope data, i.e. fused navigation solutions can be computed (status is 3).
- IMU-mount alignment coarse calibration ongoing (only supported in protocol versions 19+):
 Once initialized (status is 3), the automatic IMU-mount alignment engine has sufficient
 confidence in all IMU-mount misalignment angles and validates their use for compensating the
 accelerometer and gyroscope data (fused navigation solutions can be computed). The engine
 keeps filtering the IMU-mount misalignment angles every time the observed vehicle dynamics
 allows for it.
- IMU-mount alignment fine calibration ongoing (only supported in protocol versions 19+): Once the IMU-mount misalignment angles are estimated with a good accuracy, the automatic IMU-mount alignment engine becomes more conservative in updating the IMU-mount misalignment angles (status is 4).

29.5.3.3 Alignment Errors

The following errors might be output in the error bitfield of the UBX-ESF-ALG message:

- IMU-mount misalignment angle error (only supported in protocol versions 15.01 to 17): If the automatic IMU-mount alignment engine suspects wrong IMU-mount misalignment angles (either due to a wrong initialization or a change in the physical mounting of the device), the error bit 0 in the UBX-ESF-ALG message is set.
- IMU-mount roll/pitch angle error (only supported in protocol versions 19+): If the automatic IMU-mount alignment engine suspects wrong IMU-mount roll and/or IMU-mount pitch misalignment angles (either due to a wrong initialization or a change in the physical mounting of

the device), the error bit 0 in the UBX-ESF-ALG message is set.

- **IMU-mount yaw angle error** (only supported in protocol versions 19+): If the automatic IMU-mount alignment engine suspects wrong IMU-mount yaw misalignment angle (either due to a wrong initialization or a change in the physical mounting of the device), the error bit 1 in the UBX-ESF-ALG message is set.
- Euler Angle singularity ('gimbal-lock') error (only supported in protocol versions 19+): The Euler angle singularity error bit 2 is set when the automatic IMU-mount alignment engine detects an installation where the IMU-frame is misaligned in such a way that a degree of freedom is lost when two IMU-mount misalignment (Euler) angles begin to describe the same rotations (or axes). This happens for example with an IMU-mount misalignment of +/- 90 degrees around the IMU-mount pitch axis, where IMU-mount roll and IMU-mount yaw cannot be distinguished from each other. In such a case, these IMU-mount misalignment angles start to heavily fluctuate with time due to the mathematical singularity occurring at these points, meaning that the IMU-mount misalignment angles output in the UBX-ESF-ALG are not stable in time. Note however that each individual set of IMU-mount misalignment angles output in such a case still describes the correct rotation. Moreover, the internal rotation applied for aligning the IMU readings doesn't suffer from this singularity issue and optimal fusion can still be achieved.

29.5.4 Navigation Output

(Only supported in protocol versions 19+).

29.5.4.1 Local-level North-East-Down (NED) Frame

The local-level frame is a geodetic frame with following features:

- The origin (O) is a point on the Earth surface;
- The x-axis points to North;
- the y-axis points to East;
- the z-axis completes the right-handed reference system by pointing down.

The frame is referred to as North-East-Down (NED) since its axes are aligned with the North, East and Down directions.

29.5.4.2 Body-Frame

The body-frame is a right-handed 3D Cartesian frame rigidly connected with the vehicle and is used to determine the attitude of the vehicle with respect to the local-level frame. It has the following features:

- The origin (O) is the origin of the IMU instrumental frame;
- The x-axis points towards the front of the vehicle;
- the y-axis points towards the right of the vehicle;
- the z-axis completes the right-handed reference system by pointing down.

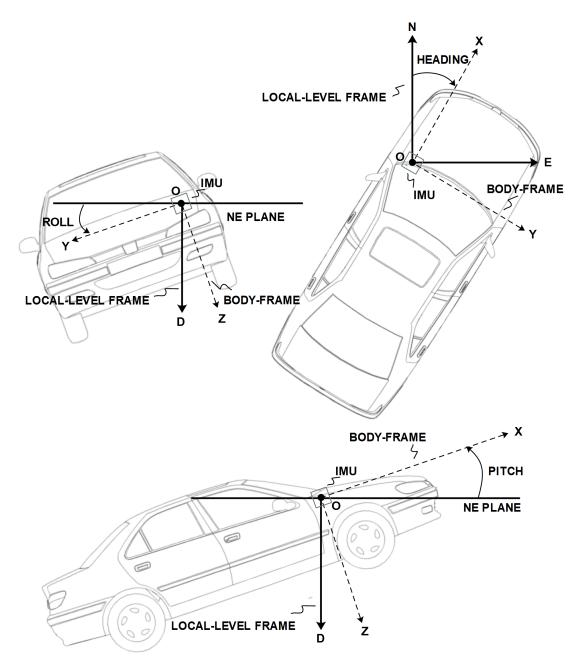

29.5.4.3 Vehicle Position and Velocity Output

The position and velocity information is output in several messages like UBX-NAV-PVT for example. The position computed by the UDR navigation filter is referenced to the origin (O) of the body-frame.

29.5.4.4 Vehicle Attitude Output

The transformation between the body-frame and the local-level frame is described by three attitude angles about the local-level axes denoted as vehicle roll, vehicle pitch and vehicle heading. All three angles are referred as vehicle attitude and are illustrated in the figure below:

NOTES: N = NORTH, E = EAST, D = DOWN, IMU-FRAME ALIGNED WITH BODY-FRAME

The order of the sequence of rotations around the navigation axes defining the vehicle attitude matrix in terms of vehicle attitude angles is illustrated below:

VEHICLE ATTITUDE DEFINITION

 ϕ : Vehicle roll angle

heta : Vehicle pitch angle

 ψ : Vehicle heading angle

 \mathbf{C}_{b}^{n} : Rotation between body-frame (b) and local-level NED navigation-frame (n)

$$\mathbf{C}_X = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos(\phi) & \sin(\phi) \\ 0 & -\sin(\phi) & \cos(\phi) \end{bmatrix} \quad \mathbf{C}_Y = \begin{bmatrix} \cos(\theta) & 0 & -\sin(\theta) \\ 0 & 1 & 0 \\ \sin(\theta) & 0 & \cos(\theta) \end{bmatrix} \quad \mathbf{C}_Z = \begin{bmatrix} \cos(\psi) & \sin(\psi) & 0 \\ -\sin(\psi) & \cos(\psi) & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

$$\begin{split} \mathbf{C}_b^n &= \mathbf{C}_Z^T \cdot \mathbf{C}_Y^T \cdot \mathbf{C}_X^T \\ &= \begin{bmatrix} \cos{(\theta)}\cos{(\psi)} & \sin{(\phi)}\sin{(\theta)}\cos{(\psi)} - \cos{(\phi)}\sin{(\psi)} & \cos{(\phi)}\sin{(\theta)}\cos{(\psi)} + \sin{(\phi)}\sin{(\psi)} \\ \cos{(\theta)}\sin{(\psi)} & \sin{(\phi)}\sin{(\phi)}\sin{(\psi)} + \cos{(\phi)}\cos{(\psi)} & \cos{(\phi)}\sin{(\theta)}\sin{(\psi)} - \sin{(\phi)}\cos{(\psi)} \\ -\sin{(\phi)} & \sin{(\phi)}\cos{(\theta)} & \cos{(\phi)}\cos{(\phi)} \end{bmatrix} \end{split}$$

The vehicle attitude is output in the UBX-NAV-ATT message. The message provides all three angles together with their accuracy estimates. Note that since no backwards motion information is measured, no heading of motion information is output in the UBX-NAV-PVT message (heading of vehicle is provided in a separate field within the same message).

29.5.4.5 Vehicle Dynamics Output

The UBX-ESF-INS message outputs information about vehicle dynamics provided by the INS: compensated vehicle angular rates and compensated vehicle accelerations. The acceleration data is free of any gravitational acceleration. It's accuracy is directly dependent on the filter attitude estimation accuracy.

Compensated vehicle dynamics information is output with respect to the body-frame.

29.5.5 Sensor Data Types

The supported sensor data types are:

Definition of Data Types

| Туре | Description | Unit | Format of the 24 data bits |
|------|-----------------------------------|--------------|----------------------------|
| 0 | none, data field contains no data | | |
| 14 | reserved | | |
| 5 | z-axis gyroscope angular rate | deg/s *2^-12 | signed |
| 6 | front-left wheel ticks | | Bits 0-22: unsigned |
| | | | tick value. Bit 23: |
| | | | direction indicator |
| | | | (0=forward, |
| | | | 1=backward) |

| | | | tick value. Bit 23: |
| | | | direction indicator |
| | | | (0=forward, |
| | | | 1=backward) |
| 11 | speed | m/s * 1e-3 | signed |
| 12 | gyroscope temperature | deg Celsius * 1e- | signed |
| | | 2 | |
| 13 | y-axis gyroscope angular rate | deg/s *2^-12 | signed |
| 14 | x-axis gyroscope angular rate | deg/s *2^-12 | signed |
| 16 | x-axis accelerometer specific force | m/s^2 *2^-10 | signed |
| 17 | y-axis accelerometer specific force | m/s^2 *2^-10 | signed |
| 18 | z-axis accelerometer specific force | m/s^2 *2^-10 | signed |

29.5.6 Raw Sensor Data Output

(This feature is not supported in protocol versions less than 15.01).

Some u-blox module products contain inertial sensors (IMU) that are directly connected to the GNSS and cannot be directly accessed from outside the module. The UBX-ESF-RAW message can be used to access raw measurements of these sensors. A variable number of data fields may be used in a single message and these can contain different types of measurements. The type of each measurement is specified in the dataType field. The possible data types are x, y and z-axis measurements on gyroscope or accelerometer and gyroscope temperature measurements as described in the ESF Measurement Data section. One UBX-ESF-RAW message can contain multiple samples from the same sensor. The user can separate and order these using the time tags attached to each of the measurements.

The measurements are made at a fixed rate. The sampling rate or other sensor configuration options can not be changed.

To turn on this feature the UBX-ESF-RAW message must be enabled using UBX-CFG-MSG. If non-zero rate is selected the message will be output but the selected rate does not otherwise have an

influence at the rate of the messages.

Turning on this feature does not disable sensor fusion in the receiver. To use an external fusion algorithm consider disabling the automotive dead reckoning mode using UBX-CFG-NAVX5.

29.5.7 Receiver Startup and Shutdown

Continuous dead reckoning is possible over receiver restarts if the following conditions are true:

- · Non-volatile storage is available, or the save-on-shutdown feature (SOS) is used
- · The vehicle is not moved while the receiver is off

During periods of external sensor data unavailability the receiver switches to GNSS-only navigation if the last sensor information indicated the vehicle was moving.

30 High Navigation Rate (HNR)

This feature is only available with the ADR products.

This feature is only available with the UDR products.

30.1 Introduction

u-blox DR solutions allow a low latency position and velocity to be output at up to 30 Hz. The maximum GNSS rate is 2 Hz. Sensors measurements are used to propagate the solution at the higher rate between GNSS epochs.

The high navigation rate solution is output using the UBX-HNR-PVT message for firmwares using protocol version 19+.

30.2 Configuration

The high navigation rate output can be configured using the UBX-CFG-HNR message.

If a high navigation rate has been configured with UBX-CFG-HNR then the number of enabled output messages must be adjusted to keep within the maximum throughput of the interface used.

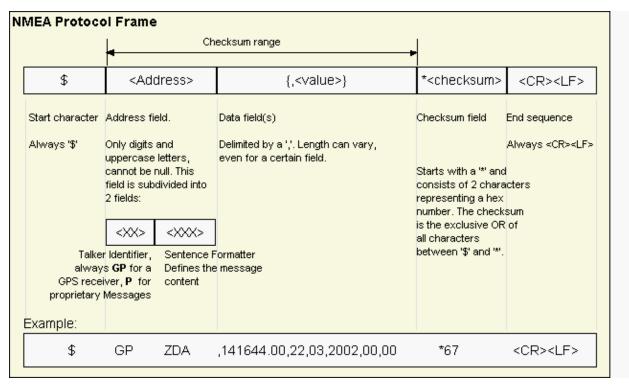

Interface Description

31 NMEA Protocol

31.1 Protocol overview

31.1.1 Message format

NMEA messages sent by the GNSS receiver are based on NMEA 0183 Version 4.10. The following figure shows the structure of a NMEA protocol message.

For further information on the NMEA Standard, refer to NMEA 0183 Standard For Interfacing Marine Electronic Devices, Version 4.10, June, 2012. See http://www.nmea.org/ for ordering instructions.

The NMEA standard allows for proprietary, manufacturer-specific messages to be added. These shall be marked with a manufacturer mnemonic. The mnemonic assigned to u-blox is UBX and is used for all non-standard messages. These proprietary NMEA messages therefore have the address field set to PUBX. The first data field in a PUBX message identifies the message number with two digits.

31.1.2 Talker ID

One of the ways the NMEA standard differentiates between GNSS is by using a two-letter message identifier, the 'Talker ID'. The specific Talker ID used by a u-blox receiver will depend on the device model and system configuration. The table below shows the Talker ID that will be used for various GNSS configurations.

NMEA Talker IDs

| Configured GNSS | Talker ID |
|-------------------------|-----------|
| GPS, SBAS, QZSS | GP |
| GLONASS | GL |
| Galileo | GA |
| BeiDou | GB* |
| Any combination of GNSS | GN |

^{*}This is a u-blox extension to the NMEA 4.10 standard. Only NMEA 4.11 defines the GB talker ID. See also Extended Configuration in Protocol Configuration.

31.1.3 Protocol configuration

The NMEA protocol on u-blox receivers can be configured to the need of customer applications using UBX-CFG-NMEA. For backwards compatibility various versions of this message are supported, however, any new users should use the version that is not marked as deprecated.

There are four NMEA standards supported. The default NMEA version is 4.10. Alternatively versions 4.00, 2.3, and 2.1 can be enabled (for details on how this affects the output refer to section Position Fix Flags in NMEA Mode).

Customers using BeiDou and/or Galileo are recommended to select NMEA version 4.10, as earlier versions have no support for these two GNSS.

Customers using High Precision GNSS (HPG) products are recommended to select NMEA version 4.10, as earlier versions do no support the Float RTK (F) and Real Time Kinematic (R) mode indicator flags in all messages.

NMEA defines satellite numbering systems for some, but not all GNSS (this is partly dependent on the NMEA version). Satellite numbers for unsupported GNSS can be configured using UBX-CFG-NMEA. Unknown satellite numbers are always reported as a null NMEA field (i.e. an empty string).

The NMEA specification indicates that the GGA message is GPS-specific. However, u-blox receivers support the output of a GGA message for each of the Talker IDs.

NMEA filtering flags

| • • | |
|--------------------|---|
| Parameter | Description |
| Position filtering | Enable positions from failed or invalid fixes to be reported (with the "V" status |
| | flag to indicate that the data is not valid). |
| Valid position | Enable positions from invalid fixes to be reported (with the "V" status flag to |
| filtering | indicate that the data is not valid). |
| Time filtering | Enable the receiver's best knowledge of time to be output, even though it |
| | might be wrong. |
| Date filtering | Enable the receiver's best knowledge of date to be output, even though it |
| | might be wrong. |
| GPS-only filtering | Restrict output to GPS satellites only. |
| Track filtering | Permit course over ground (COG) to be reported even when it would otherwise |
| | be frozen. |

NMEA flags

| Parameter | Description |
|-----------|-------------|

NMEA flags continued

| Parameter | Description | | |
|----------------|---|--|--|
| Compatibility | Some older NMEA applications expect the NMEA output to be formatted in a | | |
| Mode | specific way, for example, they will only work if the latitude and longitude have | | |
| | exactly four digits behind the decimal point. u-blox receivers offer a | | |
| | compatibility mode to support these legacy applications. | | |
| Consideration | u-blox receivers use a sophisticated signal quality detection scheme, in order | | |
| Mode | to produce the best possible position output. This algorithm considers all SV | | |
| | measurements, and may eventually decide to only use a subset thereof, if it | | |
| | improves the overall position accuracy. If Consideration Mode is enabled, all | | |
| | satellites, which were considered for navigation, are communicated as being | | |
| | used for the position determination. If Consideration Mode is disabled, only | | |
| | those satellites which after the consideration step remained in the position | | |
| | output are marked as being used. | | |
| Limit82 Mode | Enabling this mode will limit the NMEA sentence length to a maximum of 82 | | |
| | characters. | | |
| High Precision | Enabling this mode increases precision of the position output. Latitude and | | |
| Mode | longitude then have seven digits after the decimal point, and altitude has | | |
| | three digits after the decimal point. Note: The High Precision Mode cannot be | | |
| | set in conjunction with either Compatibility Mode or Limit82 Mode. | | |

Extended configuration

| Option | Description | | |
|----------------|---|--|--|
| GNSS to filter | Filters satellites based on their GNSS | | |
| Satellite | This field configures the display of satellites that do not have an NMEA- | | |
| numbering | defined value. Note: this does not apply to satellites with an unknown ID. | | |
| Main Talker ID | By default the main Talker ID (i.e. the Talker ID used for all messages other | | |
| | than GSV) is determined by the GNSS assignment of the receiver's channels | | |
| | (see UBX-CFG-GNSS). This field enables the main Talker ID to be overridden. | | |
| GSV Talker ID | By default the Talker ID for GSV messages is GNSS-specific (as defined by | | |
| | NMEA). This field enables the GSV Talker ID to be overridden. | | |
| BDS Talker ID | By default the Talker ID for BeiDou is 'GB'. This field enables the BeiDou Talker | | |
| | ID to be overridden. | | |

Extra fields in NMEA 4.10 and above

| Message | Extra fields |
|---------|--------------------|
| GBS | systemId, signalId |
| GNS | navStatus |
| GRS | systemId, signalId |
| GSA | systemId |
| GSV | signalld |
| RMC | navStatus |

31.1.4 Satellite numbering

The NMEA protocol (V4.10) identifies GNSS satellites with a one digit system ID and a two digit satellite number. u-blox receivers support this method in their NMEA output when "strict" SV numbering is selected.

In most cases this is the default setting, but can be checked or set using UBX-CFG-NMEA.

In order to support QZSS within current receivers and prepare for support of other systems (e.g. Galileo) in future receivers, an "extended" SV numbering scheme can be enabled (using UBX-CFG-NMEA).

This uses the NMEA-defined numbers where possible, but adds other number ranges to support other GNSS. Note however that these non-standard extensions require 3 digit numbers, which may not be supported by some NMEA parsing software. For example QZSS satellites are reported using numbers in the range 193 to 197.

See Satellite Numbering for a complete list of satellite numbers.

GLONASS satellites can be tracked before they have been identified. In NMEA output, such unknown satellite numbers are always reported as a null field (i.e. an empty string).

31.1.5 Latitude and longitude format

According to the NMEA Standard, Latitude and Longitude are output in the format of Degrees, Minutes and (Decimal) Fractions of Minutes. To convert to Degrees and Fractions of Degrees, or Degrees, Minutes, Seconds and Fractions of seconds, the 'Minutes' and 'Fractional Minutes' parts need to be converted. In other words: If the GPS Receiver reports a Latitude of 4717.112671 North and Longitude of 00833.914843 East, this is

Latitude 47 Degrees, 17.112671 Minutes

Longitude 8 Degrees, 33.914843 Minutes

Latitude 47 Degrees, 17 Minutes, 6.76026 Seconds

31.1.6 Position fix flags

This section shows how u-blox implements the NMEA protocol and the conditions determining how flags are set.

Flags in NMEA 4.10 and above

| NMEA Message | GLL, RMC | GGA | GLL, VTG | RMC, GNS |
|--|---------------|-----------|-----------|-----------|
| Field | status | quality | posMode | posMode |
| No position fix (at power-up, after losing satellite lock) | V | 0 | N | N |
| GNSS fix, but user limits exceeded | V | 0 | N | N |
| Dead reckoning fix, but user limits exceeded | V | 6 | Е | E |
| Dead reckoning fix | А | 6 | E | E |
| RTK float | Α | 5 | D | F |
| RTK fixed | А | 4 | D | R |
| 2D GNSS fix | А | 1/2 | A/D | A/D |
| 3D GNSS fix | Α | 1/2 | A/D | A/D |
| Combined GNSS/dead reckoning fix | Α | 1/2 | A/D | A/D |
| | See below (1) | See below | See below | See below |
| | | (2) | (3) | (3) |

- (1) Possible values for status: V = Data invalid, A = Data valid
- (2) Possible values for quality: 0 = No fix, 1 = Autonomous GNSS fix, 2 = Differential GNSS fix, 4 = RTK fixed, 5 = RTK float, 6 = Estimated/Dead reckoning fix
- (3) Possible values for posMode: N = No fix, E = Estimated/Dead reckoning fix, A = Autonomous GNSS fix, D = Differential GNSS fix, F = RTK float, R = RTK fixed

Flags in NMEA 2.3 and above

| NMEA Message | GLL, RMC | GGA | GSA | GLL, VTG, |
|--|---------------|-----------|-----------|-----------|
| | | | | RMC, GNS |
| Field | status | quality | navMode | posMode |
| No position fix (at power-up, after losing satellite lock) | V | 0 | 1 | N |
| GNSS fix, but user limits exceeded | V | 0 | 1 | N |
| Dead reckoning fix, but user limits exceeded | V | 6 | 2 | E |
| Dead reckoning fix | А | 6 | 2 | E |
| 2D GNSS fix | А | 1/2 | 2 | A/D |
| 3D GNSS fix | А | 1/2 | 3 | A/D |
| Combined GNSS/dead reckoning fix | А | 1/2 | 3 | A/D |
| | See below (1) | See below | See below | See below |
| | | (2) | (3) | (4) |

- (1) Possible values for status: V = Data invalid, A = Data valid
- (2) Possible values for quality: 0 = No fix, 1 = Autonomous GNSS fix, 2 = Differential GNSS fix, 4 = RTK fixed, 5 = RTK float, 6 = Estimated/Dead reckoning fix
- (3) Possible values for navMode: 1 = No fix, 2 = 2D fix, 3 = 3D fix
- (4) Possible values for posMode: N = No fix, E = Estimated/Dead reckoning fix, A = Autonomous GNSS fix, D = Differential GNSS fix, F = RTK float, R = RTK fixed

Flags in NMEA 2.1 and below

The flags in NMEA 2.1 and below are the same as NMEA 2.3 and above but with the following differences:

- The posMode field is not output for GLL, RMC and VTG messages (each message has one field less).
- The GGA quality field is set to 1 (instead of 6) for both types of dead reckoning fix.

31.1.7 Multi-GNSS considerations

Many applications which process NMEA messages assume that only a single GNSS is active. However, when multiple GNSS are configured, the NMEA specification requires the output to change in the following ways:

NMEA output for Multi-GNSS

| Change | Description |
|----------------|---|
| Main Talker ID | The main Talker ID will be 'GN' (e.g. instead of 'GP' for a GPS receiver) |
| GSV Talker IDs | The GSV message reports the signal strength of the visible |
| | satellites. However, the Talker ID it uses is specific to the GNSS it is |
| | reporting information for, so for a multi-GNSS receiver it will not be |
| | the same as the main Talker ID (e.g. other messages will be using the |
| | 'GN' Talker ID but the GSV message will use GNSS-specific Talker |
| | IDs). |

NMEA output for Multi-GNSS continued

| Change | Description |
|----------------------|---|
| Multiple GSA and GRS | Multiple GSA and GRS messages are output for each fix, one for |
| Messages | each GNSS. This may confuse applications which assume they are |
| | output only once per position fix (as is the case for a single GNSS |
| | receiver). |

31.1.8 Output of invalid/unknown data

By default the receiver will not output invalid data. In such cases, it will output empty fields.

A valid position fix is reported as follows:

\$GPGLL,4717.11634,N,00833.91297,E,124923.00,A,A*6E

An invalid position fix (but time valid) is reported as follows:

\$GPGLL,,,,,124924.00,V,N*42

If Time is unknown (e.g. during a cold start):

\$GPGLL,,,,,,V,N*64

Note:

An exception from the above default are dead reckoning fixes, which are also output when invalid (user limits exceeded).

Tip Differing from the NMEA standard, u-blox reports valid dead reckoning fixes with user limits met (not exceeded) as valid (A) instead of invalid (V).

Output of invalid data marked with the 'Invalid/Valid' Flags can be enabled using the UBX protocol message UBX-CFG-NMEA.

31.1.9 Messages overview

When configuring NMEA messages using the UBX protocol message UBX-CFG-MSG, the Class/Ids shown in the table shall be used.

| Page | Mnemonic | Cls/ID | Description | |
|------|------------------------|-----------|--|--|
| | NMEA Standard Messages | | Standard messages | |
| 145 | DTM | 0xF0 0x0A | Datum reference | |
| 146 | GBQ | 0xF0 0x44 | Poll a standard message (Talker ID GB) | |

31.2 Standard Messages

Standard messages: i.e. Messages as defined in the NMEA standard.

31.2.1 DTM

31.2.1.1 Datum reference

| Message | DTM | | | | | |
|--------------|-----------------|---|---|--|--|--|
| Description | Datum refere | Datum reference | | | | |
| Firmware | Supported on | Supported on: | | | | |
| | • u-blox 8 / u- | blox M8 protoc | ol versions 15, 15.01, 16, 17, 18, 19, 19.1, 19.2, 20, 20.01, | | | |
| | 20.1, 20.2, 2 | 0.3, 22, 22.01, 2 | 23 and 23.01 | | | |
| Туре | Output | | | | | |
| Comment | This message | gives the diffe | rence between the current datum and the reference | | | |
| | datum. | | | | | |
| | The current d | The current datum is set to WGS84 by default. | | | | |
| | The reference | The reference datum cannot be changed and is always set to WGS84. | | | | |
| | ID for CFG-MSG | Number of fields | | | | |
| Message Info | 0xF0 0x0A | 11 | | | | |

Message Structure:

\$xxDTM,datum,subDatum,lat,NS,lon,EW,alt,refDatum*cs<CR><LF>

Example:

\$GPDTM, W84,,0.0,N,0.0,E,0.0,W84*6F

\$GPDTM,999,,0.08,N,0.07,E,-47.7,W84*1C

| Field | Name | Unit | Format | Example | Description |
|-------|--------------------|------|-------------|---------|--|
| No. | | | | | |
| 0 | xxDTM | - | string | \$GPDTM | DTM Message ID (xx = current Talker ID, see |
| | | | | | NMEA Talker IDs table) |
| 1 | datum | - | string | W84 | Local datum code: W84 = WGS84, P90 = |
| | | | | | PZ90 (supported in protocol versions greater |
| | | | | | than 19.1), 999 = user-defined |
| 2 | subDatum | - | string | - | A null field |
| 3 | lat | min | numeric | 0.08 | Offset in Latitude |
| 4 | NS | - | character | S | North/South indicator |
| 5 | lon | min | numeric | 0.07 | Offset in Longitude |
| 6 | EW | - | character | E | East/West indicator |
| 7 | alt | m | numeric | -2.8 | Offset in altitude |
| 8 | refDatum | - | string | W84 | Reference datum code: W84 (WGS 84, fixed |
| | | | | | field) |
| 9 | cs | - | hexadecimal | *67 | Checksum |
| 10 | <cr><lf></lf></cr> | - | character | - | Carriage return and line feed |

31.2.2 GBQ

31.2.2.1 Poll a standard message (Talker ID GB)

| Message | GBQ | | | | |
|--------------|--|--|--|--|--|
| Description | Poll a standard message (Talker ID GB) | | | | |
| Firmware | Supported on: | | | | |
| | • u-blox 8 / u-blox M8 protocol versions 15, 15.01, 16, 17, 18, 19, 19.1, 19.2, 20, 20.01, | | | | |
| | 20.1, 20.2, 20.3, 22, 22.01, 23 and 23.01 | | | | |
| Туре | Poll Request | | | | |
| Comment | Polls a standard NMEA message if the current Talker ID is GB | | | | |
| | ID for CFG-MSG Number of fields | | | | |
| Message Info | 0xF0 0x44 4 | | | | |

Message Structure:

\$xxGBQ,msgId*cs<CR><LF>

Example:

| \$EIGE | \$EIGBQ,RMC*28 | | | | | |
|--------|--------------------|------|-------------|---------|--|--|
| Field | Name | Unit | Format | Example | Description | |
| No. | | | | | | |
| 0 | xxGBQ | - | string | \$EIGBQ | GBQ Message ID (xx = Talker ID of the device | |
| | | | | | requesting the poll) | |
| 1 | msgId | - | string | RMC | Message ID of the message to be polled | |
| 2 | cs | - | hexadecimal | *28 | Checksum | |
| 3 | <cr><lf></lf></cr> | - | character | - | Carriage return and line feed | |

31.2.3 GBS

31.2.3.1 GNSS satellite fault detection

| Message | GBS |
|-------------|--|
| Description | GNSS satellite fault detection |
| Firmware | Supported on: • u-blox 8 / u-blox M8 protocol versions 15, 15.01, 16, 17, 18, 19, 19.1, 19.2, 20, 20.01, 20.1, 20.2, 20.3, 22, 22.01, 23 and 23.01 |
| Туре | Output |
| Comment | This message outputs the results of the Receiver Autonomous Integrity Monitoring Algorithm (RAIM). The fields errLat, errLon and errAlt output the standard deviation of the position calculation, using all satellites that pass the RAIM test successfully. The fields errLat, errLon and errAlt are only output if the RAIM process passed successfully (i.e. no or successful edits happened). These fields are never output if 4 or fewer satellites are used for the navigation calculation (because, in such cases, integrity cannot be determined by the receiver autonomously). The fields prob, bias and stdev are only output if at least one satellite failed in the RAIM test. If more than one satellites fail the RAIM test, only the information for the worst |
| | satellite is output in this message. ID for CFG-MSG Number of fields |
| | TOTOL GEG-INIGO INCIDEL OF HEIDS |

| Message Info | 0xF0 0x09 | 13 | |
|--------------|-----------|----|--|
| | | | |

Message Structure:

 $\verb|xxxGBS|, time, errLat, errLon, errAlt, svid, prob, bias, stddev, systemId, signalId*cs<CR><LF>| and time | arrLon |$

Example:

\$GPGBS,235503.00,1.6,1.4,3.2,,,,*40

\$GPGBS,235458.00,1.4,1.3,3.1,03,,-21.4,3.8,1,0*5B

| ŞGPGI | GPGBS, 235458.UU, 1.4, 1.3, 3.1, U3, , -21.4, 3.8, 1, U^5B | | | | | | |
|--------------|--|------|-------------|-----------|---|--|--|
| Field No. | Name | Unit | Format | Example | Description | | |
| 0 | xxGBS | - | string | \$GPGBS | GBS Message ID (xx = current Talker ID, see NMEA Talker IDs table) | | |
| 1 | time | - | hhmmss.ss | 235503.00 | UTC time to which this RAIM sentence belongs. See section UTC representation in the integration manual for details. | | |
| 2 | errLat | m | numeric | 1.6 | Expected error in latitude | | |
| 3 | errLon | m | numeric | 1.4 | Expected error in longitude | | |
| 4 | errAlt | m | numeric | 3.2 | Expected error in altitude | | |
| 5 | svid | - | numeric | 03 | Satellite ID of most likely failed satellite | | |
| 6 | prob | - | numeric | - | Probability of missed detection: null (not supported, fixed field) | | |
| 7 | bias | m | numeric | -21.4 | Estimated bias of most likely failed satellite (a priori residual) | | |
| 8 | stddev | m | numeric | 3.8 | Standard deviation of estimated bias | | |
| 9 | systemId | - | hexadecimal | 1 | NMEA-defined GNSS system ID, see Signal Identifiers table (only available in NMEA 4.10 and later) | | |
| 10 | signalId | - | hexadecimal | 0 | NMEA-defined GNSS signal ID, see Signal Identifiers table (only available in NMEA 4.10 and later) | | |

| 12 | <cr><lf></lf></cr> | - | character | _ | Carriage return and line feed | | |

31.2.4 GGA

31.2.4.1 Global positioning system fix data

| Message | GGA | | | | |
|-------------|---|--|--|--|--|
| Description | Global positioning system fix data | | | | |
| Firmware | Supported on: • u-blox 8 / u-blox M8 protocol versions 15, 15.01, 16, 17, 18, 19, 19.1, 19.2, 20, 20.01, 20.1, 20.2, 20.3, 22, 22.01, 23 and 23.01 | | | | |
| Туре | Output | | | | |
| Comment | The output of this message is dependent on the currently selected datum (default: WGS84). The NMEA specification indicates that the GGA message is GPS-specific. However, when the receiver is configured for multi-GNSS, the GGA message contents will be generated from the multi-GNSS solution. For multi-GNSS use, it is recommended that the NMEA-GNS message is used instead. | | | | |

| | Time and position, together with GPS fixing-related data (number of satellites in use, and the resulting HDOP, age of differential data if in use, etc.). | | | | | | |

32 UBX Protocol

32.1 UBX Protocol Key Features

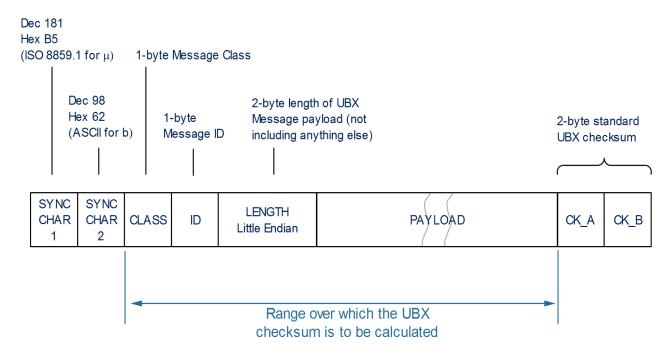

u-blox receivers support a u-blox proprietary protocol to communicate with a host. This protocol has the following key features:

- Compact uses 8-bit binary data.
- Checksum protected uses a low-overhead checksum algorithm
- Modular uses a 2-stage message identifier (Class and Message ID)

32.2 UBX Frame Structure

The structure of a basic UBX Frame is shown in the following diagram.

- Every **Frame** starts with a 2-byte Preamble consisting of two synchronization characters: 0xB5 0x62.
- A 1-byte Message Class field follows. A Class is a group of messages that are related to each other.
- A 1-byte Message ID field defines the message that is to follow.
- A 2-byte Length field follows. The length is defined as being that of the payload only. It does not
 include the Preamble, Message Class, Message ID, Length, or Cyclic Redundancy Check (CRC)
 fields. The number format of the length field is a Little-Endian unsigned 16-bit integer.
- The **Payload** field contains a variable number of bytes.
- The two 1-byte **CK_A** and **CK_B** fields hold a 16-bit checksum whose calculation is defined below. This concludes the Frame.

32.3 UBX Payload Definition Rules

32.3.1 Structure Packing

Values are placed in such an order that structure packing is not a problem. This means that 2-byte values shall start on offsets which are a multiple of 2; 4-byte values shall start at a multiple of 4; and so on.

32.3.2 Reserved Elements

Some messages contain reserved fields or bits to allow for future expansion. The contents of these elements should be ignored in output messages and must be set to zero in input messages. Where a message is output and subsequently returned to the receiver as an input message, reserved elements can either be explicitly set to zero or left with whatever value they were output with.

32.3.3 Undefined Values

The description of some fields provides specific meanings for specific values. For example, the field gnssld appears in many UBX messages and uses 0 to indicate GPS, 1 for SBAS and so on (see Satellite Numbering for details); however it is usually stored in a byte with far more possible values than the handful currently defined. All such undefined values are reserved for future expansion and therefore should not be used.

32.3.4 Message Naming

Referring to messages is done by adding the class name and a dash in front of the message name. For example, the version information message is referred to as <code>UBX-MON-VER</code>. Referring to message fields or their values is done by adding a dot and the name, e.g. <code>UBX-MON-VER</code>. swVersion.

32.3.5 Number Formats

All multi-byte values are ordered in Little Endian format, unless otherwise indicated.

All floating point values are transmitted in IEEE754 single or double precision.

Variable Type Definitions

| Short | Туре | Size | Comment | Min/Max | Resolution |
|-------|----------------|---------|-------------------|----------------|-------------------|
| | | (Bytes) | | | |
| U1 | Unsigned Char | 1 | | 0255 | 1 |

The description of some integer values (e.g. U2, I4 or I8) indicates a fixed-point format (e.g. [UU.FF], [IIIII.FFF] or [IIIIIII.FFFFFFFF]). The fixed-point value can be retrieved from the integer value by first casting it to appropriate type (e.g. as a floating-point number) and then scaling it with the indicated scaling factor.

32.4 UBX Checksum

The checksum is calculated over the Message, starting and including the CLASS field up until, but excluding, the Checksum Field:

The checksum algorithm used is the 8-Bit Fletcher Algorithm, which is used in the TCP standard (RFC 1145). This algorithm works as follows:

- Buffer[N] contains the data over which the checksum is to be calculated.
- The two CK_ values are 8-Bit unsigned integers only! If implementing with larger-sized integer values, make sure to mask both CK_A and CK_B with 0xFF after both operations in the loop.

```
CK_A = 0, CK_B = 0
For(I=0;I<N;I++)
{</pre>
```

```
CK_A = CK_A + Buffer[I]

CK_B = CK_B + CK_A
}
```

 After the loop, the two U1 values contain the checksum, transmitted after the Message, which conclude the Frame.

32.5 UBX Message Flow

There are certain features associated with the messages being sent back and forth:

32.5.1 Acknowledgement

When messages from the class CFG are sent to the receiver, the receiver will send an "acknowledge" (UBX-ACK-ACK) or a "not acknowledge" (UBX-ACK-NAK) message back to the sender, depending on whether or not the message was processed correctly.

Some messages from other classes (e.g. LOG) also use the same acknowledgement mechanism.

32.5.2 Polling Mechanism

All messages that are output by the receiver in a periodic manner (i.e. messages in classes MON, NAV and RXM) and Get/Set type messages, such as the messages in the CFG class, can also be polled.

The UBX protocol is designed so that messages can be polled by sending the message required to the receiver but without a payload (or with just a single parameter that identifies the poll request). The receiver then responds with the same message with the payload populated.

32.6 UBX Class IDs

A class is a grouping of messages which are related to each other. The following table lists all the current message classes.

| Name | Class | Description | | | | | | | | |
|------|-------|---|--|--|--|--|--|--|--|--|
| NAV | 0x01 | Navigation Results Messages: Position, Speed, Time, Acceleration, Heading, DOP, | | | | | | | | |
| | | SVs used | | | | | | | | |
| RXM | 0x02 | Receiver Manager Messages: Satellite Status, RTC Status | | | | | | | | |
| INF | 0x04 | Information Messages: Printf-Style Messages, with IDs such as Error, Warning, | | | | | | | | |
| | | Notice | | | | | | | | |
| ACK | 0x05 | Ack/Nak Messages: Acknowledge or Reject messages to UBX-CFG input messages | | | | | | | | |
| CFG | 0x06 | Configuration Input Messages: Configure the receiver | | | | | | | | |
| UPD | 0x09 | Firmware Update Messages: Memory/Flash erase/write, Reboot, Flash | | | | | | | | |
| | - | identification, etc | | | | | | | | |
| MON | 0x0A | Monitoring Messages: Communication Status, Stack Usage, Task Status | | | | | | | | |
| AID | 0x0B | AssistNow Aiding Messages: Ephemeris, Almanac, other A-GPS data input | | | | | | | | |
| TIM | 0x0D | Timing Messages: Time Pulse Output, Time Mark Results | | | | | | | | |
| ESF | 0x10 | External Sensor Fusion Messages: External Sensor Measurements and Status | | | | | | | | |
| | • | Information | | | | | | | | |
| MGA | 0x13 | Multiple GNSS Assistance Messages: Assistance data for various GNSS | | | | | | | | |
| LOG | 0x21 | Logging Messages: Log creation, deletion, info and retrieval | | | | | | | | |
| SEC | 0x27 | Security Feature Messages | | | | | | | | |
| HNR | 0x28 | High Rate Navigation Results Messages: High rate time, position, speed, heading | | | | | | | | |
| | • | | | | | | | | | |

All remaining class IDs are reserved.

32.7 UBX Messages Overview

| Comment | | All UBX-AID messages are deprecated; use UBX-MGA messages instead | | | | | | | | | | | |
| | | All UBX-AID messages are deprecated; use UBX-MGA messages instead SF1D0 to SF3D7 is only sent if ephemeris is available for this SV. If not, the payload may be reduced to 8 Bytes, or all bytes are set to zero, indicating this SV Number does not have valid ephemeris for the moment. This may happen even if NAV-SVINFO and RXM-SVSI are indicating ephemeris availability as the internal data may not represent the content of an original broadcast ephemeris (or only parts thereof). SF1D0 to SF3D7 contain the 24 words following the Hand-Over Word (How from the GPS navigation message, subframes 1 to 3. The Truncated TOV Count is not valid and cannot be used. See IS-GPS-200 for a full descript the contents of the Subframes. In SF1D0 to SF3D7, the parity bits have been removed, and the 24 bits of are located in Bits 0 to 23. Bits 24 to 31 shall be ignored. When polled, the data contained in this message does not represent the original ephemeris broadcast. Some fields that are irrelevant to u-blox | | | | | | If not, the dicating that This may meris f an original Vord (HOW) ated TOW description of | | | | | |

| Comment | | <u> </u> | | | | | | netood | | | | |
| Comment | | Th cartin int int | All UBX-AID messages are deprecated; use UBX-MGA messages instead This message contains position, time and clock drift information. The position be input in either the ECEF X/Y/Z coordinate system or as lat/lon/height ime can either be input as inexact value via the standard communication interface, suffering from latency depending on the baud rate, or using hard immession where an accurate time pulse is input on the external interrupts. It is also possible to supply hardware frequency aiding by connect a continuous signal to an external interrupt. Header Class ID Length (Bytes) Payload Checksum | | | | | | The position on/height. The ication ing hardware external | | | |

32.10 UBX-CFG (0x06)

Configuration Input Messages: i.e. Configure the receiver.

Messages in the CFG class can be used to configure the receiver and poll current configuration values. Any messages in the CFG class sent to the receiver are either acknowledged (with message UBX-ACK-ACK) if processed successfully or rejected (with message UBX-ACK-NAK) if processing unsuccessfully.

Bitfield flags

This graphic explains the bits of flags

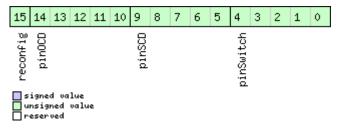

| Name | Description |
|--------------|---|
| isCalibrated | 1 if the oscillator gain is calibrated, 0 if not |
| controlIf | Communication interface for oscillator control: |
| | 0: Custom DAC attached to receiver's I2C |
| | 1: Microchip MCP4726 (12 bit DAC) attached to receiver's I2C |
| | 2: TI DAC8571 (16 bit DAC) attached to receiver's I2C |
| | 13: 12 bit DAC attached to host |
| | 14: 14 bit DAC attached to host |
| | 15: 16 bit DAC attached to host |
| | Note that for DACs attached to the host, the host must monitor UBX-TIM-DOSC messages and pass |
| | the supplied raw values on to the DAC. |

|-------------------|------------------|---------|---------------|---------------|---|--|--|--|
| Byte Offset | Number Format | Scaling | Name | Unit | Description | | | |
| 0 | U1 | - | version | - | Message version (0x00 for this version) | | | |
| 1 | X1 | - | flags1 | - | Flags (see graphic below) | | | |
| 2 | X1 | - | flags2 | - | Flags (see graphic below) | | | |
| 3 | U1[1] | - | reserved1 | - | Reserved | | | |
| 4 | U4 | 1e-6 | wtFactor | - | Wheel-tick scale factor to obtain distance [m] from wheel-ticks (0 = not set) | | | |
| 8 | U4 | 1e-6 | wtQuantError | m (or m/s) | Wheel-tick quantization. If useWtSpeed is set then this is interpreted as the speed measurement error RMS. | | | |
| 12 | U4 | - | wtCountMax | - | Wheel-tick counter maximum value (rollover - 1). If null, relative wheel-tick counts are assumed (and therefore no rollover). If not null, absolute wheel-tick counts are assumed and the value corresponds to the highest tick count value before rollover happens. If useWtSpeed is set then this value is ignored. If value is set to 1, absolute wheel-tick counts are assumed and the value will be automatic calculated if possible. It is only possible for automatic calibration to calculate wtCntMax if it can be represented as a number of set bits (i.e. 2^N). If it cannot be represented in this way it must be set to the correct absolute tick value manually. | | | |
| 16 | U2 | - | wtLatency | ms | Wheel-tick data latency due to e.g. CAN bus | | | |
| 18 | U1 | - | wtFrequency | Hz | Nominal wheel-tick data frequency (0 = not set) | | | |
| 19 | X1 | - | flags3 | - | Flags (see graphic below) | | | |
| 20 | U2 | - | speedDeadBand | cm/s | Speed sensor dead band (0 = not set) | | | |
| 22 | U1[10] | - | reserved2 | - | Reserved | | | |

Bitfield flags1

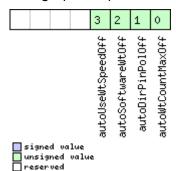

This graphic explains the bits of flags1

| Name | Description |
|--------------|--|
| combineTicks | Use combined rear wheel-ticks instead of the single tick |
| useWtSpeed | Use speed measurements (data type 11 in ESF-MEAS) instead of single ticks (data type 10) |
| dirPinPol | Only supported on certain products. |
| | Direction pin polarity |
| | 0: High signal level means forward direction, |
| | 1: High signal level means backward direction. |
| useWtPin | Use wheel-tick pin for speed measurement. |

Bitfield flags2

This graphic explains the bits of flags2

| Name | Description |
|---------------|---|
| autoWtCountMa | Disable automatic estimation of maximum absolute wheel-tick counter value (0: enabled, 1: |
| xOff | disabled). See wtCountMax field description for more details. |
| | (Not supported in protocol versions less than 19) |
| autoDirPinPol | Only supported on certain products. |
| Off | Disable automatic wheel-tick direction pin polarity detection (0: enabled, 1: disabled). See dirPinPol |
| | field description for more details. |
| | (Not supported in protocol versions less than 19) |
| autoSoftwareW | Only supported on certain products. |
| tOff | Disable automatic use of wheel-tick or speed data received over the software interface if available (0: |
| | enabled, 1: disabled). In this case, data coming from the hardware interface (wheel-tick pins) will |
| | automatically be ignored if wheel-tick/speed data are available from the software interface. See |
| | useWtPin field description for more details. |
| | (Not supported in protocol versions less than 19) |

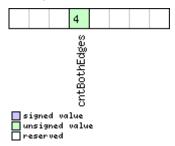

Bitfield flags2 Description continued

| Name | Description |
|---------------|---|
| autoUseWtSpee | Disable automatic receiver reconfiguration for processing speed data instead of wheel-tick data if no |
| dOff | wheel-tick data are available but speed data were detected (0: enabled, 1: disabled). See useWtSpeed |
| | field description for more details. |
| | (Not supported in protocol versions less than 19) |

Bitfield flags3

This graphic explains the bits of flags3

| Name | Description |
|--------------|--|
| cntBothEdges | Only supported on certain products. |
| | Count both rising and falling edges on wheel-tick signal (only relevant if wheel-tick is measured by |
| | the u-blox receiver). |
| | Only turn on this feature if the wheel-tick signal has 50 % duty cycle. Turning on this feature with |
| | fixed-width pulses can lead to severe degradation of performance. |
| | Use wheel-tick pin for speed measurement. This field can only be used with modules supporting |
| | analog wheel-tick signals. |

32.10.13 UBX-CFG-GNSS (0x06 0x3E)

32.10.13.1 GNSS system configuration

| Message | UBX-CFG-GNSS | | | | | | | |
|-------------|---|--|--|--|--|--|--|--|
| Description | GNSS system configuration | | | | | | | |
| Firmware | Supported on: | | | | | | | |
| | • u-blox 8 / u-blox M8 protocol versions 15, 15.01, 16, 17, 18, 19, 19.1, 19.2, 20, 20.01, | | | | | | | |
| | 20.1, 20.2, 20.3, 22, 22.01, 23 and 23.01 | | | | | | | |
| Туре | Get/set | | | | | | | |
| Comment | Gets or sets the GNSS system channel sharing configuration. | | | | | | | |
| | If the receiver is sent a valid new configuration, it will respond with a UBX-ACK | | | | | | | |
| | ACK message and immediately change to the new configuration. Otherwis | | | | | | | |
| | receiver will reject the request, by issuing a UBX-ACK-NAK and continuing | | | | | | | |
| | operation with the previous configuration. | | | | | | | |
| | Configuration requirements: | | | | | | | |
| | • It is necessary for at least one major GNSS to be enabled, after applying the | | | | | | | |
| | new configuration to the current one. | | | | | | | |
| | It is also required that at least 4 tracking channels are available to each | | | | | | | |
| | enabled major GNSS, i.e. maxTrkCh must have a minimum value of 4 for each | | | | | | | |
| | enabled major GNSS. | | | | | | | |
| | The number of tracking channels in use must not exceed the number of | | | | | | | |

tracking channels available in hardware, and the sum of all reserved tracking channels needs to be less than or equal to the number of tracking channels in use.

Notes:

- To avoid cross-correlation issues, it is recommended that GPS and QZSS are always both enabled or both disabled.
- Polling this message returns the configuration of all supported GNSS, whether
 enabled or not; it may also include GNSS unsupported by the particular
 product, but in such cases the enable flag will always be unset.
- See section GNSS Configuration for a discussion of the use of this message.
- See section Satellite Numbering for a description of the GNSS IDs available.
- Applying the GNSS system configuration takes some time. After issuing UBX-CFG-GNSS, wait first for the acknowledgement from the receiver and then 0.5 seconds before sending the next command.
- If Galileo is enabled, UBX-CFG-GNSS must be followed by UBX-CFG-CFG to save current configuration to BBR and then by UBX-CFG-RST with resetMode set to Hardware reset.
- Configuration specific to the GNSS system can be done via other messages (e. g. UBX-CFG-SBAS).

32.10.17 UBX-CFG-LOGFILTER (0x06 0x47)

32.10.17.1 Data logger configuration

| Message | | UB | X-CFG-L | OGFI | LTER | | | | | |
|----------------|------|---|---|--------|-----------------------|---------------------|---------|--|---------|-----------|
| Description | | Da | ta logge | r conf | igurat | ion | | | | |
| Firmware | | • (| Supported on: • u-blox 8 / u-blox M8 protocol versions 15, 15.01, 16, 17, 18, 19, 19.1, 19.2, 20, 20.01, 20.1, 20.2, 20.3, 22, 22.01, 23 and 23.01 | | | | | | | |
| Туре | | <u> </u> | Get/set | | | | | | | |
| Comment | | This message can be used to configure the data logger, i.e. to enable/disable the log recording and to get/set the position entry filter settings. Position entries can be filtered based on time difference, position difference or current speed thresholds. Position and speed filtering also have a minimum time interval. A position is logged if any of the thresholds are exceeded. If a threshold is set to zero it is ignored. The maximum rate of position logging is 1 Hz. The filter settings will be configured to the provided values only if the 'applyAllFilterSettings' flag is set. This allows the recording to be enabled/disabled independently of configuring the filter settings. Configuring the data logger in the absence of a logging file is supported. By doing so, once the logging file is created, the data logger configuration will take effect immediately and logging recording and filtering will activate according to | | | | | | | | |

32.10.27 UBX-CFG-RATE (0x06 0x08)

32.10.27.1 Navigation/measurement rate settings

| Message | | UB | UBX-CFG-RATE | | | | | | | | | | |
|---------------|-------|--|---|-------|-------|--------|-----------|-----|-----------|-----------|--|--|--|
| Description | | Na | vigation | /meas | surem | ent ra | te settir | ngs | | | | | |
| Firmware | | • (| Supported on: • u-blox 8 / u-blox M8 protocol versions 15, 15.01, 16, 17, 18, 19, 19.1, 19.2, 20, 20.01, 20.1, 20.2, 20.3, 22, 22.01, 23 and 23.01 | | | | | | | | | | |
| Туре | | Ge | Get/set | | | | | | | | | | |
| Comment | | This message allows the user to alter the rate at which navigation solutions (and the measurements that they depend on) are generated by the receiver. The calculation of the navigation solution will always be aligned to the top of a second zero (first second of the week) of the configured reference time system. (Navigation period is an integer multiple of the measurement period in protocol versions greater than 17). • Each measurement triggers the measurements generation and, if available, raw data output. • The navRate value defines that every nth measurement triggers a navigation epoch. • The update rate has a direct influence on the power consumption. The more fixes that are required, the more CPU power and communication resources are required. • For most applications a 1 Hz update rate would be sufficient. • When using power save mode, measurement and navigation rate can differ from the values configured here. | | | | | | | | | | | |
| | | Hea | ader | Class | ID | Length | (Bytes) | | Payload | Checksum | | | |

UBX-CFG-RATE continued

| Byte Offset | Number Format | Scaling | Name | Unit | Description |
|-------------|------------------|---------|------------|--------|--|
| 0 | U2 | - | measRate | ms | The elapsed time between GNSS |
| | 02 | - | lileaskace | 1113 | measurements, which defines the rate, e. |
| | | | | | g. 100 ms => 10 Hz, 1000 ms => 1 Hz, |
| | | | | | 10000 ms => 0.1 Hz. Measurement rate |
| | | | | | should be greater than or equal to 25 ms. |
| | | | | | (Measurement rate should be greater |
| | | | | | than or equal to 50 ms in protocol versions |
| | | | | | less than 24). |
| 2 | U2 | - | navRate | cycles | The ratio between the number of |
| | | | | | measurements and the number of |
| | | | | | navigation solutions, e.g. 5 means five |
| | | | | | measurements for every navigation |
| | | | | | solution. Maximum value is 127. (This |
| | | | | | parameter is ignored and the navRate is |
| | | | | | fixed to 1 in protocol versions less than 18). |
| 4 | U2 | - | timeRef | - | The time system to which measurements |
| | | | | | are aligned: |
| | | | | | 0: UTC time |
| | | | | | 1: GPS time |
| | | | | | 2: GLONASS time (not supported in |
| | | | | | protocol versions less than 18) |

| Name | Description |
|---------------|--|
| disableIntern | 1 = disable disciplining of the internal oscillator |
| al | |
| disableExtern | 1 = disable disciplining of the external oscillator |
| al | |
| preferenceMod | Reference selection preference |
| е | 0 - best frequency accuracy |
| | 1 - best phase accuracy |
| enableGNSS | 1 = enable use of GNSS as synchronization source |
| enableEXTINT0 | 1 = enable use of EXTINTO as synchronization source |
| enableEXTINT1 | 1 = enable use of EXTINT1 as synchronization source |
| enableHostMea | 1 = enable use of host measurements on the internal oscillator as synchronization source |
| sInt | Measurements made by the host must be sent to the receiver using a UBX-TIM-SMEAS-DATA0 |
| | message. |
| enableHostMea | 1 = enable use of host measurements on the external oscillator as synchronization source |
| sExt | Measurements made by the host must be sent to the receiver using a UBX-TIM-SMEAS-DATA0 |
| | message. |
| useAnyFix | 0 - use over-determined navigation solutions only |
| | 1- use any fix |
| disableMaxSle | 0 - use the value in the field maxSlewRate for maximum time correction in corrective time pulse |
| wRate | mode |
| | 1- don't use the value in the field maxSlewRate |
| issueFreqWarn | 1 = issue a warning (via UBX-TIM-TOS flag) when frequency uncertainty exceeds freqTolerance |
| ing | |
| issueTimeWarn | 1 = issue a warning (via UBX-TIM-TOS flag) when time uncertainty exceeds timeTolerance |
| ing | |
| TPCoherent | Control time pulse coherency |
| | 0 - Coherent pulses. Time phase offsets will be corrected gradually by varying the GNSS oscillator |
| | rate within frequency tolerance limits. There will always be the correct number of GNSS oscillator |
| | cycles between time pulses. Given tight limits this may take a long time |
| | 1 - Non-coherent pulses. In this mode the receiver will correct time phase offsets as quickly as |
| | allowed by the specified maximum slew rate, in which case there may not be the expected number of |
| | GNSS oscillator cycles between time pulses. |
| | 2 - Post-initialization coherent pulses. The receiver will run in non-coherent mode as described above |
| | until the pulse timing has been corrected and PLL is active on the internal oscillator, but will then |
| | switch to coherent pulse mode. |
| disableOffset | 1 = disable automatic storage of oscillator offset |

| le time pulse; if pin assigned to another function, other function takes precedence. | | | | | | | | |
|---|--|--|--|--|--|--|--|--|
| la time pulse; if his assigned to another function, other function takes precedence | | | | | | | | |
| te time pulse, if pin assigned to another runction, other runction takes precedence. | | | | | | | | |
| et for FTS variant. | | | | | | | | |
| If set, synchronize time pulse to GNSS as soon as GNSS time is valid. If not set, or before GNSS time | | | | | | | | |
| e local clock. | | | | | | | | |
| ignored by the FTS product variant; in this case the receiver always locks to the best | | | | | | | | |
| me/frequency reference (which is not necessarily GNSS). | | | | | | | | |
| an be unset only in Timing product variants. | | | | | | | | |
| eceiver switches between the timepulse settings given by 'freqPeriodLocked' & | | | | | | | | |
| ocked' and those given by 'freqPeriod' & 'pulseLen'. The 'Locked' settings are used where | | | | | | | | |
| r has an accurate sense of time. For non-FTS products, this occurs when GNSS solution | | | | | | | | |
| ble time is available, but for FTS products the setting syncMode field governs behavior. In | | | | | | | | |
| he receiver only uses 'freqPeriod' & 'pulseLen' when the flag is unset. | | | | | | | | |
| PeriodLock' and 'freqPeriod' are interpreted as frequency, otherwise interpreted as period. | | | | | | | | |
| eLenRatioLock' and 'pulseLenRatio' interpreted as pulse length, otherwise interpreted as | | | | | | | | |
| | | | | | | | | |
| to top of second (period time must be integer fraction of 1s). | | | | | | | | |
| ckGnssFreq' to use this feature. | | | | | | | | |
| ignored by the FTS product variant; it is assumed to be always set (as is lockGnssFreq). | | | | | | | | |
| ewRate and maxPhaseCorrRate fields of UBX-CFG-SMGR to 0 to disable alignment. | | | | | | | | |
| rity: | | | | | | | | |
| dge at top of second | | | | | | | | |
| ge at top of second | | | | | | | | |
| | | | | | | | | |

Bitfield flags Description continued

| Name | Description |
|-------------|--|
| gridUtcGnss | Timegrid to use: |
| | 0: UTC |
| | 1: GPS |
| | 2: GLONASS |
| | 3: BeiDou |
| | 4: Galileo (not supported in protocol versions less than 18) |
| | This flag is only relevant if 'lockGnssFreq' and 'alignToTow' are set. |
| | Note that configured GNSS time is estimated by the receiver if locked to any GNSS system. If the |
| | receiver has a valid GNSS fix it will attempt to steer the TP to the specified time grid even if the |
| | specified time is not based on information from the constellation's satellites. To ensure timing based |
| | purely on a given GNSS, restrict the supported constellations in UBX-CFG-GNSS. |
| syncMode | Sync Manager lock mode to use: |
| | 0: switch to 'freqPeriodLock' and 'pulseLenRatioLock' as soon as Sync Manager has an accurate |
| | time, never switch back to 'freqPeriod' and 'pulseLenRatio' |
| | 1: switch to 'freqPeriodLock' and 'pulseLenRatioLock' as soon as Sync Manager has an accurate |
| | time, and switch back to 'freqPeriod' and 'pulseLenRatio' as soon as time gets inaccurate |
| | This field is only relevant for the FTS product variant. |
| | This field is only relevant if the flag 'lockedOtherSet' is set. |

| Name | Description |
|--------------|---|
| tiltAlgError | IMU-mount tilt (roll and/or pitch) alignment error (0: no error, 1: error) |
| yawAlgError | IMU-mount yaw alignment error (0: no error, 1: error) |
| angleError | IMU-mount misalignment Euler angle singularity error (0: no error, 1: error). If this error bit is set, the |
| | IMU-mount roll and IMU-mount yaw angles cannot uniquely be defined due to the singularity issue |
| | happening with installations mounted with a +/- 90 degrees misalignment around pitch axis. This is |
| | also known as the 'gimbal-lock' problem affecting rotations described by Euler angles. |

32.11.2 UBX-ESF-INS (0x10 0x15)

Bitfield initStatus1

This graphic explains the bits of ${\tt initStatus1}$

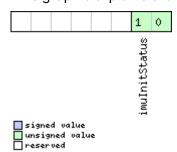

| Name | Description |
|---------------|---|
| wtInitStatus | Wheel tick factor initialization status (0: off, 1: initializing, 2: initialized). |
| mntAlgStatus | Automatic IMU-mount alignment status (0: off, 1: initializing, 2: initialized, 3: initialized). |
| insInitStatus | INS initialization status (0: off, 1: initializing, 2: initialized). |

Bitfield initStatus2

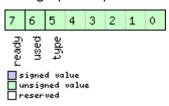

This graphic explains the bits of initStatus2

| Name | Description |
|---------------|--|
| imuInitStatus | IMU initialization status (0: off, 1: initializing, 2: initialized). |

Bitfield sensStatus1

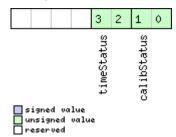

This graphic explains the bits of sensStatus1

| Name | Description |
|-------|--|
| type | Sensor data type. See section Sensor data types in the integration manual for details. |
| used | If set, sensor data is used for the current sensor fusion solution. |
| ready | If set, sensor is set up (configuration is available or not required) but not used for computing the |
| | current sensor fusion solution. |

Bitfield sensStatus2

This graphic explains the bits of sensStatus2

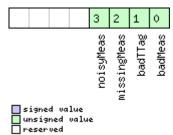

| Name | Description |
|-------------|---|
| calibStatus | 00: Sensor is not calibrated |
| | 01: Sensor is calibrating |
| | 10/11: Sensor is calibrated |
| | Good dead reckoning performance is only possible when all used sensors are calibrated. Depending |
| | on the quality of the GNSS signals and the sensor data, the sensors may take a longer time to get |
| | calibrated. |
| timeStatus | 00: No data |
| | 01: Reception of the first byte used to tag the measurement |
| | 10: Event input used to tag the measurement |
| | 11: Time tag provided with the data |

Bitfield faults

This graphic explains the bits of faults

| Name | Description |
|-------------|--|
| badMeas | Bad measurements detected |
| badTTag | Bad measurement time-tags detected |
| missingMeas | Missing or time-misaligned measurements detected |
| noisyMeas | High measurement noise-level detected |

32.12 UBX-HNR (0x28)

High Rate Navigation Results Messages: i.e. High rate time, position, speed, heading. Messages in the HNR class are used to output high rate navigation data for position, altitude, velocity and their accuracies.

Bitfield valid

This graphic explains the bits of valid

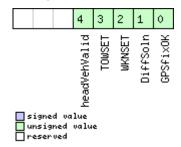

| Name | Description |
|---------------|---|
| validDate | 1 = Valid UTC Date (see Time Validity section in the integration manual for details) |
| validTime | 1 = Valid UTC Time of Day (see Time Validity section in the integration manual for details) |
| fullyResolved | 1 = UTC Time of Day has been fully resolved (no seconds uncertainty) |

Bitfield flags

This graphic explains the bits of flags

| Name | Description |
|--------------|--|
| GPSfixOK | >1 = Fix within limits (e.g. DOP & accuracy) |
| DiffSoln | 1 = DGPS used |
| WKNSET | 1 = Valid GPS week number |
| TOWSET | 1 = Valid GPS time of week (iTOW & fTOW) |
| headVehValid | 1= Heading of vehicle is valid |

32.13 UBX-INF (0x04)

Information Messages: i.e. Printf-Style Messages, with IDs such as Error, Warning, Notice. Messages in the INF class are used to output strings in a printf style from the firmware or application code. All INF messages have an associated type to indicate the kind of message.

32.13.1 UBX-INF-DEBUG (0x04 0x04)

32.14.4 UBX-LOG-FINDTIME (0x21 0x0E)

32.14.4.1 Find index of a log entry based on a given time

| Message | UBX-LOG-FINDTIME |
|-------------|---|
| Description | Find index of a log entry based on a given time |
| Firmware | Supported on: • u-blox 8 / u-blox M8 protocol versions 15, 15.01, 16, 17, 18, 19, 19.1, 19.2, 20, 20.01, 20.1, 20.2, 20.3, 22, 22.01, 23 and 23.01 |
| Туре | Input |
| Comment | This message can be used for a time-based search of a log. It can find the index of the first log entry with time equal to the given time, otherwise the index of the most recent entry with time less than the given time. This index can then be used with the UBX-LOG-RETRIEVE message to provide time-based retrieval of log entries. Searching a log is effective for a given time later than the base date (January 1st, 2004). Searching a log for a given time earlier than the base date will result in an 'entry not found' response. (Searching a log for a given time earlier than the base date will result in a UBX-ACK-NAK message in protocol versions less than 18). Searching a log for a given time greater than the last recorded entry's time will return the index of the last recorded entry. (If the logging has stopped due to lack of file space, such a search will result in a UBX-ACK-NAK message in |

| | | pro | otocol ve | rsions | less t | than 18 | 3). | | | | |

| Description | | Lo | g inform | ation | | | | | | | | |
| Firmware | | • (| pported u-blox 8 / 20.1, 20.2 | u-blo | | | | ns 15, 15.01, 16, 17, 18, 3.01 | 19, 19.1, 1 | 9.2, 20, 20.01, | | |
| Туре | | | tput | | | | | | | | | |
| Comment | | No l l t t | This message is used to report information about the logging subsystem. Note: The reported maximum log size will be smaller than that originally specified in LOG-CREATE due to logging and filestore implementation overheads. Log entries are compressed in a variable length fashion, so it may be difficult to predict log space usage with any precision. There may be times when the receiver does not have an accurate time (e.g. if the week number is not yet known), in which case some entries will not have a timestamp. This may result in the oldest/newest entry time values not taking account of these entries. | | | | | | | | | |

| This message is used to transfer a block of MGA-ANO data from host to the receiver. Upon reception of this message, the receiver will write the payload to its internal non-volatile memory (flash). Also, on reception of the first M FLASH-DATA message, the receiver will erase the flash allocated to storing existing MGA-ANO data. The payload can be up to 512 bytes. Payloads large than this would exceed the receiver's internal buffering capabilities. The rewill ACK/NACK this message using the message alternatives given below. host shall wait for an acknowledge message before sending the next data See Flash-based AssistNow Offline for details. | | | | | | | | payload data first MGA- o storing any ads larger s. Bitfield flags

This graphic explains the bits of flags

| Name | Description |
|--------------|---|
| rtcCalib | RTC is calibrated |
| safeBoot | Safeboot mode (0 = inactive, 1 = active) |
| jammingState | Output from jamming/interference monitor (0 = unknown or feature disabled or flag unavailable, 1 = |
| | ok - no significant jamming, 2 = warning - interference visible but fix OK, 3 = critical - interference |
| | visible and no fix). This flag is deprecated in protocol versions that support UBX-SEC-SIG (version |
| | 0x02) and always reported as 0; instead jammingState in UBX-SEC-SIG should be monitored. |
| xtalAbsent | RTC xtal has been determined to be absent (not supported in protocol versions less than 18) |

32.17 UBX-NAV (0x01)

Navigation Results Messages: i.e. Position, Speed, Time, Acceleration, Heading, DOP, SVs used. Messages in the NAV class are used to output navigation data such as position, altitude and velocity in a number of formats. Additionally, status flags and accuracy figures are output. The messages are generated with the configured navigation/measurement rate.

| 8 | U4 | | - | ttff | ++ff | | | | output (see graphic below) Time to first fix (millisecond time tag) | | |
| 12 | U4 | | - _ | msss | | | ms ms | | | | |
| 16 | 104 | | Ľ | ແລສະ | • | | 1113 | Milliseconds since Startup / Reset | | | |

Bitfield flags

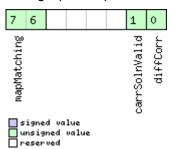

| Name | Description |
|----------|--|
| gpsFixOk | 1 = position and velocity valid and within DOP and ACC Masks. |
| diffSoln | 1 = differential corrections were applied |
| wknSet | 1 = Week Number valid (see Time Validity section for details) |
| towSet | 1 = Time of Week valid (see Time Validity section for details) |

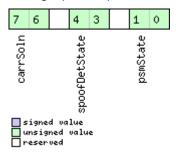

Bitfield fixStat

This graphic explains the bits of fixStat

| Name | Description | | | | | |
|---------------|--|--|--|--|--|--|
| diffCorr | 1 = differential corrections available | | | | | |
| carrSolnValid | 1 = valid carrSoln | | | | | |
| mapMatching | map matching status: | | | | | |
| | 00: none | | | | | |
| | 01: valid but not used, i.e. map matching data was received, but was too old | | | | | |
| | 10: valid and used, map matching data was applied | | | | | |
| | 11: valid and used, map matching data was applied. In case of sensor unavailability map matching | | | | | |
| | data enables dead reckoning. This requires map matched latitude/longitude or heading data. | | | | | |

Bitfield flags2

| Name | Description | | | | | | | |
|---------------|--|--|--|--|--|--|--|--|
| psmState | power save mode state | | | | | | | |
| | 0: ACQUISITION [or when psm disabled] | | | | | | | |
| | TRACKING | | | | | | | |
| | 2: POWER OPTIMIZED TRACKING | | | | | | | |
| | 3: INACTIVE | | | | | | | |
| spoofDetState | Spoofing detection state (not supported in protocol versions less than 18) | | | | | | | |
| | 0: Unknown or deactivated | | | | | | | |
| | 1: No spoofing indicated | | | | | | | |
| | 2: Spoofing indicated | | | | | | | |
| | 3: Multiple spoofing indications | | | | | | | |
| | Note that the spoofing state value only reflects the detector state for the current navigation epoch. | | | | | | | |
| | As spoofing can be detected most easily at the transition from real signal to spoofing signal, this is | | | | | | | |
| | also where the detector is triggered the most. I.e. a value of 1 - No spoofing indicated does not mean | | | | | | | |
| | that the receiver is not spoofed, it simply states that the detector was not triggered in this epoch. | | | | | | | |
| carrSoln | Carrier phase range solution status: | | | | | | | |
| | 0: no carrier phase range solution | | | | | | | |
| | 1: carrier phase range solution with floating ambiguities | | | | | | | |
| | 2: carrier phase range solution with fixed ambiguities | | | | | | | |

Bitfield globalFlags

This graphic explains the bits of ${\tt globalFlags}$

| Name | Description |
|---------|--------------------------|
| chipGen | Chip hardware generation |
| | 0: Antaris, Antaris 4 |
| | 1: u-blox 5 |
| | 2: u-blox 6 |
| | 3: u-blox 7 |
| | 4: u-blox 8 / u-blox M8 |

Bitfield flags

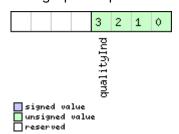

| Name | Description |
|------------|---|
| svUsed | SV is used for navigation |
| diffCorr | Differential correction data is available for this SV |
| orbitAvail | Orbit information is available for this SV (Ephemeris or Almanac) |
| orbitEph | Orbit information is Ephemeris |
| unhealthy | SV is unhealthy / shall not be used |
| orbitAlm | Orbit information is Almanac Plus |
| orbitAop | Orbit information is AssistNow Autonomous |
| smoothed | Carrier smoothed pseudorange used |

Bitfield quality

This graphic explains the bits of quality

| Name | Description | | | | | | |
|------------|---|--|--|--|--|--|--|
| qualityInd | Signal Quality indicator (range 07). The following list shows the meaning of the different QI values: | | | | | | |
| | 0: no signal | | | | | | |
| | 1: searching signal | | | | | | |
| | 2: signal acquired | | | | | | |
| | 3: signal detected but unusable | | | | | | |
| | 4: code locked and time synchronized | | | | | | |
| | 5, 6, 7: code and carrier locked and time synchronized | | | | | | |
| | Note: Since IMES signals are not time synchronized, a channel tracking an IMES signal can never | | | | | | |
| | each a quality indicator value of higher than 3. | | | | | | |

32.18.2 UBX-RXM-MEASX (0x02 0x14)

32.18.2.1 Satellite measurements for RRLP

| Message | | UBX-RXM-MEASX Satellite measurements for RRLP | | | | | | | | | | |
|---------------|-------|---|-----------|-----------|----------|----|--|--|------------|-------------|--|--|
| Description | | Satellite measurements for RRLP | | | | | | | | | | |
| Firmware | | Supported on: • u-blox 8 / u-blox M8 protocol versions 18, 19, 19.1, 19.2, 20, 20.01, 20.1, 20.2, 20, 3, 22, 22.01, 23 and 23.01 | | | | | | | | | | |
| Туре | | | riodic/Po | | | | | | | | | |
| Comment | | The message payload data is, where possible and appropriate, according to the Radio Resource LCS (Location Services) Protocol (RRLP) [1]. One exception is satellite and GNSS IDs, which here are given according to the Satellite Numbering scheme. The correct satellites have to be selected and their sate ID translated accordingly [1, tab. A.10.14] for use in a RRLP Measure Position Response Component. Similarly, the measurement reference time of week he to be forwarded correctly (modulo 14400000 for the 24 LSB GPS measurement variant, modulo 3600000 for the 22 LSB Galileo and Additional Navigation Satelllite Systems (GANSS) measurements variant) of the RRLP measure position response to the SMLC. Reference: [1] ETSI TS 144 031 V11.0.0 (2012-10), Digital cellular telecommunications system (Phase 2+), Location Services (LCS), Mobile Statement (MS) - Serving Mobile Location Centre (SMLC), Radio Resource LCS Protocol (RRLP), (3GPP TS 44.031 version 11.0.0 Release 11). | | | | | | | | | | |

| Byte Offset | Number | Scaling | Name | Unit | Description |
|-----------------|-------------|-----------|-----------|--------|--|
| Byte onset | Format | County | TVarrie | Offic | Description |
| 0 | R8 | - | rcvTow | S | Measurement time of week in receiver local time approximately aligned to the GPS time system. The receiver local time of week, week number and leap second information can be used to translate the time to other time systems. More information about the difference in time systems can be found in the RINEX 3 format documentation. For a receiver operating in GLONASS only mode, UTC time can be determined by subtracting the leapS field from GPS time regardless of whether the GPS leap seconds are valid. |
| 8 | U2 | - | week | weeks | GPS week number in receiver local time. |
| 10 | I1 | - | leapS | S | GPS leap seconds (GPS-UTC). This field represents the receiver's best knowledge of the leap seconds offset. A flag is given in the recStat bitfield to indicate if the leap seconds are known. |
| 11 | U1 | - | numMeas | - | Number of measurements to follow |
| 12 | X1 | - | recStat | - | Receiver tracking status bitfield (see graphic below) |

32.20.4 UBX-TIM-SMEAS (0x0D 0x13)

32.20.4.1 Source measurement

| Message | UBX-TIM-SMEAS |
|-------------|---|
| Description | Source measurement |
| Firmware | Supported on: |
| | • u-blox 8 / u-blox M8 protocol versions 16, 17, 18, 19, 19.1, 19.2, 20, 20.01, 20.1, 20. |
| | 2, 20.3, 22, 22.01, 23 and 23.01 (only with Time & Frequency Sync products) |
| Туре | Input/Output |
| Comment | Frequency and/or phase measurement of synchronization sources. The |
| | measurements are relative to the nominal frequency and nominal phase. |
| | The receiver reports the measurements on its sync sources using this message. |
| | Which measurements are reported can be configured using UBX-CFG-SMGR. |
| | The host may report offset of the receiver's outputs with this message as well. |
| | The receiver has to be configured using UBX-CFG-SMGR to enable the use of the |
| | external measurement messages. Otherwise the receiver will ignore them. |

| Comment | | Calibrate (measure) gain of the voltage controlled oscillator. The calibration is performed by varying the raw oscillator control values between the limits specified in raw0 and raw1. maxStepSize is the largest step change that can be used during the calibration process. The "raw values" are either PWM duty cycle values or DAC values depending on how the VCTCXO is connected to the system. The measured gain is the transfer function dRelativeFrequencyChange/dRaw (not dFrequency/dVoltage). The calibration process works as follows: Starting from the current raw output the control value is changed in the direction of raw0 in steps of size at most maxStepSize. Then the frequency is measured and the control value is changed towards raw1, again in steps of maxStepSize. When raw1 is reached, the frequency is again measured and the message version DATAO is output containing the measured result. Normal operation then resumes. If the control value movement is less than maxStepS then the transition will happen in one step - this will give fast calibration. Care must be taken when calibrating the internal oscillator against the GNSS source. In that case the changes applied to the oscillator frequency could be severe enough to lose satellite signal tracking, especially when signals are weal of the control was preciable to the unable to | | | | | | | | | imits that can be did duty cycle to the calibration In the equency is steps of red and the Normal maxStepSize ation. the GNSS could be hals are weak. e unable to his case |

33 RTCM Protocol

The RTCM (Radio Technical Commission for Maritime Services) protocol is a protocol that is used to supply the GNSS receiver with real-time differential correction data. The RTCM protocol specification is available from http://www.rtcm.org.

33.1 RTCM2

33.1.1 Introduction

This feature is only applicable to GPS operation.

This feature only supports code differential positioning.

For effective differential positioning accuracy, it is necessary that the reference station antenna is situated in a low multipath environment with an unobstructed view of the sky. It is recommended that reference receiver applies phase smoothing to the broadcast corrections.

This feature is not available with the High Precision GNSS products.

33.1.2 Supported Messages

The following RTCM 2.3 messages are supported:

Supported RTCM 2.3 Message Types

| Message | Description |
|---------|------------------------------|
| Туре | |
| 1 | Differential GPS Corrections |
| 2 | Delta Differential GPS |
| | Corrections |
| 3 | GPS Reference Station |
| | Parameters |
| 9 | GPS Partial Correction Set |

33.1.3 Configuration

The DGPS feature does not need any configuration to work properly. When an RTCM stream is input on any of the communication interfaces, the data will be parsed and applied if possible, which will put the receiver into DGPS mode.

The only configurable parameter of DGPS mode is the timeout that can be specified using UBX-CFG-NAV5. This value defines the time after which old RTCM data will be discarded.

The RTCM protocol can be disabled/enabled on communication interfaces by means of the UBX-CFG-PRT message. By default, RTCM is enabled.

33.1.4 Output

DGPS mode will result in following modified output:

NMEA-GGA: The quality field will be 2 (see NMEA Positon Fix Flags). The age of DGPS corrections
and Reference station ID will be set.

- NMEA-GLL, NMEA-RMC, NMEA-VTG, NMEA-GNS: The posMode indicator will be D (see NMEA Positon Fix Flags).
- NMEA-PUBX-POSITION: The status will be D2/D3; The age of DGPS corrections will be set.
- UBX-NAV-SOL: The DGPS flag will be set.
- UBX-NAV-PVT: The diffSoln flag will be set.
- UBX-NAV-STATUS: The diffSoln flag will be set; the diffCorr flag will be set.
- UBX-NAV-SVINFO: The DGPS flag will be set for channels with valid DGPS correction data.
- UBX-NAV-DGPS: This message will contain all valid DGPS data
- If the base line exceeds 100 km and a message type 3 is received, a UBX-INF-WARNING will be output, e.g. "WARNING: DGNSS baseline big: 330.3km"

33.1.5 Restrictions

The following restrictions apply to DGPS mode:

- The DGPS solution will only include measurements from satellites for which DGPS corrections
 were provided. This is because the navigation algorithms cannot mix corrected with uncorrected
 measurements.
- SBAS corrections will not be applied when using RTCM correction data.
- Precise Point Positioning will be deactivated when using RTCM correction data.
- RTCM correction data cannot be applied when using AssistNow Offline or AssistNow Autonomous.

33.1.6 Reference

The RTCM2 support is implemented according to RTCM 10402.3 ("RECOMMENDED STANDARDS FOR DIFFERENTIAL GNSS").

33.2 RTCM version 3

(Note: the RTCM3 protocol is not supported in protocol versions less than 20).

33.2.1 Introduction

This feature is only available with High Precision GNSS products.

This feature is only applicable to GPS, GLONASS or BeiDou operation.

This feature supports carrier phase differential positioning.

RTCM3 messages can also be transmitted through NTRIP (Networked Transport of RTCM via Internet Protocol). u-center incorporates an NTRIP client and an NTRIP server/caster.

For effective differential positioning accuracy, it is necessary that the reference station antenna is situated in a low multipath environment with an unobstructed view of the sky and continuous phase lock on all visible satellites.

33.2.2 Supported Messages

The following RTCM 3.3 input messages are supported:

Supported RTCM 3.3 Input Messages

| oupported the own old impact vices ages | | | | | | | | |
|---|--|--|--|--|--|--|--|--|
| Message Type | Description | | | | | | | |
| 1001 | L1-only GPS RTK observations | | | | | | | |

| 1125 | BeiDou MSM5 | | | | | | | |
| 1127 | BeiDou MSM7 | | | | | | | |
| 1230 | GLONASS code-phase biases | | | | | | | |
| 4072, sub-type | Reference station PVT (u-blox proprietary RTCM Message) | | | | | | | |
| 0 | | | | | | | | |
| | | | | | | | | |

The following RTCM 3.3 output messages are supported:

When configuring RTCM output messages using the UBX protocol message UBX-CFG-MSG, the Class/IDs shown in the table shall be used.

Supported RTCM 3.3 Output Messages

| • • | • | • |
|----------------|-----------|---|
| Message Type | Cls/ID | Description |
| 1005 | 0xF5 0x05 | Stationary RTK reference station ARP |
| 1074 | 0xF5 0x4A | GPS MSM4 |
| 1077 | 0xF5 0x4D | GPS MSM7 |
| 1084 | 0xF5 0x54 | GLONASS MSM4 |
| 1087 | 0xF5 0x57 | GLONASS MSM7 |
| 1124 | 0xF5 0x7C | BeiDou MSM4 |
| 1127 | 0xF5 0x7F | BeiDou MSM7 |
| 1230 | 0xF5 0xE6 | GLONASS code-phase biases |
| 4072, sub-type | 0xF5 0xFE | Reference station PVT (u-blox proprietary RTCM Message) |
| 0 | | |
| | | |

33.2.3 u-blox Proprietary RTCM Messages

The RTCM message type 4072 is the u-blox proprietary RTCM message. It is supported by the RTCM standard version 3.2 and above.

33.2.3.1 Sub-Types

There are different available sub-types of the RTCM message type 4072. The table below shows the available RTCM 4072 sub-types.

RTCM 4072 Sub-Types

| Sub- | Message Type | Sub-Type | Description | Message Data (Payload) Length (bits) |
|------|--------------|----------|----------------------|--------------------------------------|
| Туре | Number | Number | | |
| 1 | 0xFE8 | 0x001 | Additional reference | 112+48*(2*N) |
| | | | station information | (N = the number of enabled GNSS |
| | | | | constellations) |

33.2.4 Configuration

The configuration of the RTK rover and reference station is explained in the RTK Mode Configuration section.

The RTCM3 protocol can be disabled/enabled on communication interfaces by means of the UBX-CFG-PRT message. By default, RTCM3 is enabled.

The configuration of the RTCM3 correction stream must be done according to the following rules:

- The RTCM3 stream must contain a reference station message (type 1005 or type 1006) in addition to the GNSS observation messages.
- The RTCM3 stream must contain a reference station message (type 1005, type 1006, or type 4072, sub-type 0) in addition to the GNSS observation messages.
- All observation messages must be broadcast at the same rate.
- The reference station ID field in the GNSS observation messages must be consistent with the reference station ID field in the reference station message otherwise the rover will not be able to compute its position.
- The RTCM3 stream must contain the GLONASS code-phase biases message (type 1230)
 otherwise the GLONASS ambiguities can only be estimated as float unless the receiver is able
 to identify the code-phase bias from receiver descriptor message (RTCM 1033), even in RTK
 fixed mode.
- The static reference station message (type 1005 or type 1006) does not need to be broadcast at the same rate as the observation messages but the rover will not be able to compute its position until it has received a valid reference station message.
- The moving baseline reference message (type 4072, sub-type 0) must be broadcast at the same rate as the observation messages.
- The RTCM3 stream should only contain one type of observation messages per constellation.
 When using a multi-constellation configuration, all constellations should use the same type of observation messages. Mixing RTK and MSM messages will result in undefined rover behavior.
- The moving baseline reference message (type 4072, sub-type 0) should only be used in combination with MSM7 observation messages.
- If the receiver is configured to output RTCM messages on several ports, they must all have the same RTCM configuration otherwise the MSM multiple message bit might not be set properly.

33.2.5 Output

RTK Rover and MB Rover Modes will result in following modified output:

- NMEA-GGA: The quality field will be 4 for RTK fixed and 5 for RTK float (see NMEA Positon Fix Flags). The age of differential corrections and reference station ID will be set.
- NMEA-GLL, NMEA-VTG: The posMode indicator will be D for RTK float and RTK fixed (see NMEA
 Positon Fix Flags).
- NMEA-RMC, NMEA-GNS: The posMode indicator will be F for RTK float and R for RTK fixed (see NMEA Positon Fix Flags).
- UBX-NAV-PVT: The carrSoln flag will be set to 1 for RTK float and 2 for RTK fixed.
- UBX-NAV-RELPOSNED: The diffSoln and refPosValid flags will be set. The carrSoln flag will be set to 1 for RTK float and 2 for RTK fixed. In moving baseline rover mode, the isMoving flag will be set, and the refPosMiss and refObsMiss flags will be set for epochs during which extrapolated reference position or observations have been used.
- UBX-NAV-SAT: The diffCorr flag will be set for satellites with valid RTCM data. The
 rtcmCorrUsed, prCorrUsed, and crCorrUsed flags will be set for satellites for which the RTCM
 corrections have been applied. In moving baseline rover mode, the doCorrUsed flag will also be
 set.
- UBX-NAV-STATUS: The diffSoln flag will be set; the diffCorr flag will be set.
- If the baseline exceeds 10 km and a message type 1005, type 1006 or type 4072, sub-type 0 is received, a UBX-INF-WARNING will be output, e.g. "WARNING: DGNSS baseline big: 12.7km"

33.2.6 Reference

The RTCM3 support is implemented according to RTCM STANDARD 10403.3 DIFFERENTIAL GNSS (GLOBAL NAVIGATION SATELLITE SYSTEMS) SERVICES - VERSION 3.

Appendix

A Satellite Numbering

A summary of all the SV numbering schemes is provided in the following table.

Satellite numbering

| GNSS Type | SV range | UBX gnssld: | UBX svld | NMEA 2.X- | NMEA 2.X-4.0 | NMEA 4.10+ | NMEA 4.10+ |
|-----------|----------|-------------|-------------|--------------|--------------|------------|-------------|

| S | R? | 255 | | null | | null | |

B UBX and NMEA Signal Identifiers

UBX and NMEA protocols use signal identifiers (commonly abbreviated as "sigld") to distinguish between different signals from GNSS.

Signal identifiers are only valid when combined with a GNSS identifier (see above). The table below shows the range of identifiers currently supported in the firmware.

C u-blox 8 / u-blox M8 Default Settings

The default settings listed in this section apply to u-blox 8 / u-blox M8 receivers. These values assume that the default levels of the configuration pins have been left unchanged and no setting that affects the default configuration was written to the eFuse. Default settings are dependent on the configuration pin and eFuse settings. For information regarding these settings, consult the applicable data sheet.

If nothing else is mentioned, the default settings apply to u-blox 8 and u-blox M8 receivers.

C.1 Antenna Supervisor Settings (UBX-CFG-ANT)

For parameter and protocol description see section UBX-CFG-ANT.

Antenna Supervisor Default Settings

| Parameter | SPG 2.xx | SPG 3.xx, | ADR 3.xx | ADR 4.xx, | FTS 1.xx | TIM 1.0x | TIM 1.1x |
|-----------------|----------|-----------|----------|-----------|----------|----------|----------|
| | | HPG 1.xx | | UDR 1.xx | | | |
| flags-svcs | 1 | 1 | 1 | 1 | 0 | 1 | 1 |
| flags-scd | 1 | 1 | 0 | 0 | 0 | 1 | 0 |
| flags-pdwnOnSCD | 1 | 1 | 0 | 0 | 0 | 0 | 0 |
| flags-recovery | 1 | 1 | 0 | 0 | 0 | 1 | 0 |
| flags-ocd | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

Antenna Supervisor Default Settings continued

| Parameter | SPG 2.xx | SPG 3.xx, | ADR 3.xx | ADR 4.xx, | FTS 1.xx | TIM 1.0x | TIM 1.1x |
|----------------|----------|-----------|----------|-----------|----------|----------|----------|
| | | HPG 1.xx | | UDR 1.xx | | | |
| pins-pinSwitch | 16 | 16 | 16 | 16 | 31 | 16 | 16 |
| pins-pinSCD | 15 | 15 | 31 | 15 | 31 | 15 | 15 |
| pins-pinOCD | 31 | 14 | 31 | 14 | 31 | 31 | 14 |

C.2 Data Batching Settings (UBX-CFG-BATCH)

For parameter and protocol description see section UBX-CFG-BATCH.

Data Batching Default Settings

| Parameter | SPG 3.51 |
|--------------------|----------|
| flags-enable | 0 |
| flags-extraPvt | 1 |
| flags-extraOdo | 1 |
| flags-pioEnable | 0 |
| flags-pioActiveLow | 0 |
| bufSize | 0 |
| notifThrs | 0 |
| piold | 0 |

C.3 Datum Settings (UBX-CFG-DAT)

For parameter and protocol description see section UBX-CFG-DAT.

Datum Default Settings

| Datam Derault Octaings | |
|------------------------|--|
| Parameter | SPG 2.xx, SPG 3.xx, ADR 3.xx, FTS 1.xx, TIM 1.xx, ADR 4.xx, UDR 1.xx, HPG 1.xx |
| datumNum | 0 |
| datumName | WGS84 |
| majA | 6378137 |
| flat | 298.257223563 |
| dX | 0 |
| dY | 0 |
| dZ | 0 |
| rotX | 0 |
| rotY | 0 |
| rotZ | 0 |
| scale | 0 |
| | 0 0 0 |

C.4 Geofencing Settings (UBX-CFG-GEOFENCE)

For parameter and protocol description see section ${\tt UBX-CFG-GEOFENCE}.$

Geofencing Default Settings

| Parameter | SPG 2.xx, SPG 3.xx, HPG 1.xx, ADR 3.xx, ADR 4.xx, UDR 1.xx |
|-------------|--|
| numFences | 0 |
| confLvl | 0 |
| pioEnabled | 0 |
| pinPolarity | 0 |

Geofencing Default Settings continued

| Parameter | SPG 2.xx, SPG 3.xx, HPG 1.xx, ADR 3.xx, ADR 4.xx, UDR 1.xx |
|-----------|--|
| pin | 0 |

C.5 High Navigation Rate Settings (UBX-CFG-HNR)

For parameter and protocol description see section UBX-CFG-HNR.

High Navigation Rate Default Settings

| Parameter | ADR 3.xx, UDR 1.xx | ADR 4.xx |
|-------------|--------------------|----------|
| highNavRate | 0 | 10 |

C.6 GNSS System Settings (UBX-CFG-GNSS)

For parameter and protocol description see section UBX-CFG-GNSS.

GNSS System Default Settings

| Parameter | SPG 2.xx, | SPG 3.0x | ADR 4.xx, | FTS 1.xx | TIM 1.0x | TIM 1.1x, | HPG 1.xx |
|-----------------|-------------|-------------|-------------|-------------|-------------|-------------|------------|
| | ADR 3.xx | | UDR 1.xx | | | SPG 3.5x | |
| numTrkChHw | 32 | 32 | 28 | 32 | 32 | 32 | 32 |
| numTrkChUse | 32 | 32 | 28 | 32 | 32 | 32 | 28 |
| numConfigBlocks | 5 | 7 | 7 | 5 | 6 | 7 | 4 |
| gnssld | 0, 1, 3, 5, | 0, 1, 2, 3, | 0, 1, 2, 3, | 0, 1, 3, 5, | 0, 1, 3, 4, | 0, 1, 2, 3, | 0, 3, 5, 6 |
| | 6 | 4, 5, 6 | 4, 5, 6 | 6 | 5, 6 | 4, 5, 6 | |
| flags-enable | 1, 1, 0, 1, | 1, 1, 0, 0, | 1, 1, 0, 0, | 1, 0, 0, 1, | 1, 0, 0, 0, | 1, 0, 0, 0, | 1, 0, 1, 1 |
| | 1 | 0, 1, 1 | 0, 1, 1 | 1 | 1, 1 | 0, 1, 1 | |
| resTrkCh | 8, 1, 8, 0, | 8, 1, 4, 8, | 8, 1, 4, 8, | 8, 1, 8, 0, | 8, 1, 8, 0, | 8, 1, 4, 8, | 8, 8, 0, 8 |
| | 8 | 0, 0, 8 | 0, 0, 8 | 8 | 0,8 | 0, 0, 8 | |
| maxTrkCh | 16, 3, 16, | 16, 3, 8, | 16, 3, 8, | 16, 3, 16, | 16, 3, 16, | 16, 3, 8, | 16, 16, 3, |
| | 3, 14 | 16, 8, 3, | 16, 8, 3, | 3, 14 | 8, 3, 14 | 16, 8, 3, | 14 |
| | | 14 | 14 | | | 14 | |

C.7 INF Messages Settings (UBX-CFG-INF)

For parameter and protocol description see section UBX-CFG-INF.

C.7.1 UBX Protocol

INF Messages Default Settings for UBX protocol

| Parameter | SPG 2.xx, SPG 3.xx, FTS 1.xx, TIM 1.xx, HPG 1.xx, ADR 3.xx, ADR 4.xx, UDR 1.xx |
|--------------------|--|
| protocoIID | 0 |
| infMsgMask-ERROR | 0,0,0,0,0 |
| infMsgMask-WARNING | 0,0,0,0,0 |
| infMsgMask-NOTICE | 0,0,0,0,0 |
| infMsgMask-TEST | 0,0,0,0,0 |
| infMsgMask-DEBUG | 0,0,0,0,0 |

C.7.2 NMEA Protocol

INF Messages Default Settings for NMEA protocol

| Parameter | SPG 2.xx, TIM 1.0x, FTS 1.xx, | SPG 3.xx, TIM 1.1x, HPG 1.xx | ADR 4.xx, UDR 1.xx | |
|--------------------|-------------------------------|------------------------------|--------------------|--|
| | ADR 3.xx | | | |
| protocolID | 1 | 1 | 1 | |
| infMsgMask-ERROR | 1,1,1,1,1,1 | 1,1,0,1,1,0 | 1,1,0,1,1,0 | |
| infMsgMask-WARNING | 1,1,1,1,1,1 | 1,1,0,1,1,0 | 1,1,0,1,1,0 | |
| infMsgMask-NOTICE | 1,1,1,1,1,1 | 1,1,0,1,1,0 | 1,1,0,1,1,0 | |
| infMsgMask-TEST | 0,0,0,0,0 | 0,0,0,0,0 | 0,0,0,0,0 | |
| infMsgMask-DEBUG | 0,0,0,0,0 | 0,0,0,0,0 | 0,0,0,0,0 | |

C.8 Jammer/Interference Monitor Settings (UBX-CFG-ITFM)

For parameter and protocol description see section UBX-CFG-ITFM.

Jamming/Interference Monitor Default Settings

| Parameter | SPG 2.xx, SPG 3.xx, ADR 3.xx, FTS 1.xx, TIM 1.xx, ADR 4.xx, UDR 1.xx, HPG 1.xx |
|--------------------|--|
| config-bbThreshold | 3 |
| config-cwThreshold | 15 |
| config-enable | 0 |
| config2-antSetting | 0 |
| config2-enable2 | 0 |

C.9 Logging Settings (UBX-CFG-LOGFILTER)

For parameter and protocol description see section UBX-CFG-LOGFILTER.

Logging Default Settings

| 33 3 | |
|------------------------------|--|
| Parameter | SPG 2.xx, SPG 3.xx, ADR 3.xx, FTS 1.xx, TIM 1.xx, ADR 4.xx, UDR 1.xx, HPG 1.xx |
| flags-recordEnabled | 0 |
| flags- | 0 |
| psmOncePerWakupEnable | |
| d | |
| flags-applyAllFilterSettings | 0 |
| minInterval | 0 |
| timeThreshold | 0 |
| speedThreshold | 0 |
| positionThreshold | 0 |

C.10 Navigation Settings (UBX-CFG-NAV5)

For parameter and protocol description see section UBX-CFG-NAV5.

Navigation Default Settings

| Parameter | SPG 2.xx, | SPG 3.xx | ADR 4.xx, | FTS 1.xx | TIM 1.0x | TIM 1.1x | HPG 1.xx |
|-----------------|-----------|----------|-----------|----------|----------|----------|----------|
| | ADR 3.xx | | UDR 1.xx | | | | |
| mask-dyn | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| mask-minEl | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| mask-posFixMode | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| mask-drLim | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

Navigation Default Settings continued

| Parameter | SPG 2.xx, | SPG 3.xx | ADR 4.xx, | FTS 1.xx | TIM 1.0x | TIM 1.1x | HPG 1.xx |
|---------------------|-----------|----------|-----------|----------|----------|----------|----------|
| | ADR 3.xx | | UDR 1.xx | | | | |

| aopOrbMaxErr | 100 | 100 | 100 | 100 | 100 | 100 |
| useAdr | 1 | 1 | 1 | 1 | 0 | 0 |

wknRollover default value depends on the firmware build date.

C.12 NMEA Protocol Settings (UBX-CFG-NMEA)

For parameter and protocol description see section UBX-CFG-NMEA.

NMEA Protocol Default Settings

| Parameter | SPG 2.xx, SPG 3.xx, ADR 3.xx, FTS 1.xx, TIM 1.xx, ADR 4.xx, UDR 1.xx, HPG 1.xx |
|----------------------|--|
| filter-posFilt | 0 |
| filter-mskPosFilt | 0 |
| filter-timeFilt | 0 |
| filter-dateFilt | 0 |
| filter-gpsOnlyFilter | 0 |
| filter-trackFilt | 0 |
| nmeaVersion | 0x40 |
| numSV | 0 |
| flags-compat | 0 |
| flags-consider | 1 |
| flags-limit82 | 0 |
| flags-highPrec | 0 |
| gnssToFilter-gps | 0 |
| gnssToFilter-sbas | 0 |
| gnssToFilter-qzss | 0 |
| gnssToFilter-glonass | 0 |
| gnssToFilter-beidou | 0 |
| svNumbering | 0 |
| mainTalkerId | 0 |
| gsvTalkerId | 0 |
| bdsTalkerId | not set |

C.13 Odometer Settings (UBX-CFG-ODO)

For parameter and protocol description see section UBX-CFG-ODO.

ODO Default Settings

| Parameter | SPG 2.xx, SPG 3.0x, ADR 3.xx, FTS 1.xx, TIM 1.xx, ADR 4.xx, UDR 1.xx, HPG | SPG 3.5x |
|----------------|---|----------|
| | 1.xx | |
| flags-useODO | 0 | 1 |
| flags-useCOG | 0 | 1 |
| flags-outLPVel | 0 | 1 |
| flags-outLPCog | 0 | 1 |
| odoCfg-profile | 0 | 0 |
| cogMaxSpeed | 1 | 1 |
| cogMaxPosAcc | 50 | 50 |
| velLpGain | 153 | 153 |
| cogLpGain | 76 | 76 |

C.14 Power Management 2 Configuration (UBX-CFG-PM2)

For parameter and protocol description see section UBX-CFG-PM2.

Power Management 2 Configuration Default Settings

| Parameter | SPG 2.xx, ADR | SPG 3.0x | SPG 3.51 | TIM 1.0x | TIM 1.1x |
|----------------------|-----------------|----------|----------|----------|----------|
| | 3.xx, FTS 1.xx, | | | | |
| | ADR 4.xx, UDR | | | | |
| | 1.xx | | | | |
| maxStartupStateDur | 0 | 0 | 0 | 0 | 0 |
| flags-extintSel | 0 | 0 | 0 | 0 | 0 |

| extintlnactivityMs | n/a | 0 | 0 | n/a | 0 |

C.15 Port Configuration (UBX-CFG-PRT)

For parameter and protocol description see section UBX-CFG-PRT.

C.15.1 UART Port Configuration

For parameter and protocol description see section ${\tt UBX-CFG-PRT-UART}.$

UART 1 Default Settings

| Parameter | SPG 2.xx, SPG 3.xx, FTS 1. | ADR 3.xx, ADR 4.xx, UDR 1. | HPG 1.xx |
|-------------------------|----------------------------|----------------------------|-----------------|
| | xx, TIM 1.xx | XX | |
| txReady-en | 0 | 0 | 0 |
| txReady-pol | 0 | 0 | 0 |
| txReady-pin | 0 | 0 | 0 |
| txReady-thres | 0 | 0 | 0 |
| baudRate | 9600 | 9600 | 9600 |
| inProtoMask | inUbx,inNmea,inRtcm | inUbx,inNmea,inRtcm | inUbx,inNmea, |
| | | | inRtcm3 |
| outProtoMask | outUbx,outNmea | outUbx,outNmea | outUbx,outNmea, |
| | | | outRtcm3 |
| flags-extendedTxTimeout | 0 | 0 | 0 |

C.15.2 USB Port Configuration

For parameter and protocol description see section ${\tt UBX-CFG-PRT-USB}$.

USB Default Settings

| Parameter | SPG 2.xx, SPG 3.xx, ADR 3.xx, FTS 1.xx, TIM | HPG 1.xx |
|-------------------------|---|-------------------------|
| | 1.xx, ADR 4.xx, UDR 1.xx | |
| txReady-en | 0 | 0 |
| txReady-pol | 0 | 0 |
| txReady-pin | 0 | 0 |
| txReady-thres | 0 | 0 |
| inProtoMask | inUbx,inNmea,inRtcm | inUbx,inNmea,inRtcm3 |
| outProtoMask | outUbx,outNmea | outUbx,outNmea,outRtcm3 |
| flags-extendedTxTimeout | 0 | 0 |

C.15.3 SPI Port Configuration

For parameter and protocol description see section UBX-CFG-PRT-SPI.

SPI Default Settings

| Parameter | SPG 2.xx, SPG 3.xx, ADR 3.xx, FTS 1.xx, TIM 1.xx, ADR 4.xx, UDR 1.xx, HPG 1.xx |
|-------------------------|--|
| txReady-en | 0 |
| txReady-pol | 0 |
| txReady-pin | 0 |
| txReady-thres | 0 |
| mode-spiMode | 0 |
| mode-flowControl | 0 |
| mode-ffCnt | 0 |
| inProtoMask | None |
| outProtoMask | None |
| flags-extendedTxTimeout | 0 |

C.15.4 DDC Port Configuration

For parameter and protocol description see section UBX-CFG-PRT-DDC.

DDC Default Settings

| Parameter | SPG 2.xx, SPG 3.xx, ADR 3.xx, FTS 1.xx, TIM | HPG 1.xx |
|-------------------------|---|-------------------------|
| | 1.xx, ADR 4.xx, UDR 1.xx | |
| txReady-en | 0 | 0 |
| txReady-pol | 0 | 0 |
| txReady-pin | 0 | 0 |
| txReady-thres | 0 | 0 |
| mode-slaveAddr | 0x42 | 0x42 |
| inProtoMask | inUbx,inNmea,inRtcm | inUbx,inNmea,inRtcm3 |
| outProtoMask | outUbx,outNmea | outUbx,outNmea,outRtcm3 |
| flags-extendedTxTimeout | 0 | 0 |

C.16 Output Rate Settings (UBX-CFG-RATE)

For parameter and protocol description see section UBX-CFG-RATE.

Output Rate Default Settings

| Parameter | SPG 2.xx, SPG 3.xx, ADR 3.xx, FTS 1.xx, TIM 1.xx, ADR 4.xx, UDR 1.xx, HPG 1.xx |
|-----------|--|
| measRate | 1000 |
| navRate | 1 |
| timeRef | 1 |

C.17 Remote Inventory Settings (UBX-CFG-RINV)

For parameter and protocol description see section ${\tt UBX-CFG-RINV}.$

Remote Inventory Default Settings

| Parameter | SPG 2.xx, SPG 3.xx, ADR 3.xx, FTS 1.xx, TIM 1.xx, HPG 1.xx |
|--------------|--|
| flags-dump | 0 |
| flags-binary | 0 |

C.18 Receiver Manager Configuration Settings (UBX-CFG-RXM)

For parameter and protocol description see section UBX-CFG-RXM.

Power Management Default Settings

| Parameter | SPG 2.xx, FTS 1. | SPG 3.0x, TIM 1. | ADR 3.xx | ADR 4.xx, UDR | SPG 3.5x |
|-----------|------------------|------------------|----------|---------------|----------|
| | xx, TIM 1.0x | 1x, HPG 1.xx | | 1.xx | |
| IpMode | 0 | 0 | 0 | 0 | 1 |

C.19 SBAS Configuration Settings (UBX-CFG-SBAS)

For parameter and protocol description see section UBX-CFG-SBAS.

SBAS Configuration Default Settings

| Parameter | SPG 2.xx, | SPG 3.0x | SPG 3.5x | ADR 3.xx | ADR 4.xx, | TIM 1.1x |
|-----------------|---------------|----------|----------|----------|-----------|----------|
| | FTS 1.xx, TIM | | | | UDR 1.xx | |
| | 1.0x | | | | | |
| mode-enabled * | 1 | 1 | 1 | 1 | 1 | 0 |

Related Documents

Overview

As part of our commitment to customer support, u-blox maintains an extensive volume of technical documentation for our products. In addition to product-specific data sheets and integration manuals, general documents are also available. These include:

- GPS Compendium, GPS-X-02007
- GPS Antennas RF Design Considerations for u-blox GPS Receivers, GPS-X-08014

Our website www.u-blox.com is a valuable resource for general and product-specific documentation.

For design and integration projects the Receiver description including interface description should be used together with the Data sheet and Hardware integration manual of the GNSS receiver.

Revision History

| Revision | Date | Name | Status/Comments | | | |
|----------|-------------|---------|---|--|--|--|
| R01 | 30-Sep-2013 | efav | Added u-blox M8 firmware 2.00 | | | |
| R02 | 01-Nov-2013 | efav | Added u-blox M8 firmware 2.01 | | | |
| R03 | 15-Dec-2013 | efav | Added u-blox M8 ADR product variant | | | |
| R04 | 10-Feb-2014 | efav | Added u-blox M8 Time & Frequency Sync product variant | | | |
| R05 | 27-Jun-2014 | efav | Added u-blox M8 Timing product variant | | | |
| R06 | 09-Sep-2014 | mfre | Minor corrections | | | |
| R07 | 09-Sep-2014 | mfre | Added u-blox M8 firmware 2.30 | | | |
| R08 | 19-Nov-2014 | mfre | Added u-blox M8 L-type modules product variant | | | |
| R09 | 30-Nov-2015 | mfre | Added u-blox 8 / u-blox M8 SPG 3.01 firmware | | | |
| R10 | 15-Feb-2016 | mfre | Added u-blox 8 / u-blox M8 TIM 1.10 firmware | | | |
| R11 | 04-May-2016 | mfre | Added u-blox 8 / u-blox M8 ADR 4.00 and UDR 1.00 firmware | | | |
| R12 | 28-Apr-2017 | jhak | Added u-blox 8 / u-blox M8 ADR 4.10, HPG 1.40 and SPG 3.51 | | | |
| | • | | firmware | | | |
| R13 | 06-Jul-2017 | jhak | Added HPG 1.40 firmware information | | | |
| R14 | 24-Oct-2017 | jhak | Added ADR 4.11 firmware information | | | |
| R15 | 06-Mar-2018 | jhak | Updated Super-E messages | | | |
| R16 | 05-Nov-2018 | jhak | Added ADR 4.21 and UDR 1.21 firmware information | | | |
| R17 | 17-May-2019 | ssid | Minor corrections | | | |
| R18 | 24-Mar-2020 | ssid | Added ADR 4.31 and UDR 1.31 firmware information | | | |
| R19 | 14-May-2020 | dama | Added TIM 1.11 firmware information | | | |
| R20 | 26-Jun-2020 | ssid | Type numbers updated | | | |
| | | | NEO-M8N-0-11, NEO-M8Q-0-11, NEO-8Q-0-11, NEO-M8P-0-12, | | | |
| | | | NEO-M8P-2-12,NEO-M8T-0-11 | | | |
| R21 | 25-Sep-2020 | ssid | ADR/UDR scope changed to public, NEO-M8L added to the | | | |
| | | | product list | | | |
| | | | New messages added: UBX-CFG-ESFALG, UBX-CFG-ESFG, | | | |
| | | | UBX-CFG-ESFA, UBX-CFG-ESFWT, UBX-CFG-SENIF, UBX- | | | |
| | | | CFG-SPT, UBX-ESF-ALG, UBX-HNR-ATT, UBX-MON-SPT, UBX- | | | |
