s-center

Evaluation software for short range modules
User guide

Abstract

This document explains how to use s-center, the powerful and easy-to-use tool from u-blox for evaluation and configuration of u-blox short range, standalone modules.

1 Overview

s-center is a powerful and easy-to-use tool for evaluating, configuring, and testing u-blox short range, standalone modules running u-connectXpress software based on AT commands.

This user guide provides a description of the features of s-center and its usage for simple configuration of the u-connectXpress based module.

☞ s-center works exclusively with all u-blox standalone modules shipped with u-connectXpress wireless connectivity software. The s-center client software is not compatible for use with u-blox host-based modules.

1.1 Getting started

Having downloaded s-center client from the u-blox website and started the software, the initial display window prompts you to select a COM port, as shown in Figure 1. For new modules, you can keep the default values shown in the window. Ensure that you select the correct COM Port.

![Figure 1: Selecting COM port](image)

Once you select the COM port and click Open Port, s-center attempts to connect to the COM port. The main screen is displayed if the connection is successful, as shown in Figure 2.

If the module is in command mode, s-center reads out some information to you. s-center may additionally disable some controls if the module does not support those features.
Figure 2: Main s-center screen with some features disabled based on connected module
2 Connecting to another wireless module

2.1 Classic Bluetooth (SPP)

The act of searching for other Bluetooth devices is called an “inquiry” and is shown in Figure 3. s-center displays a list of devices that was found in a drop-down list. You can select the module you want to connect to from the list and its Bluetooth address is automatically be entered in the form, as shown in Figure 4. The Serial Port Profile (SPP) is the default protocol, so you must select Connect Peer only.

☞ The other module must have the SPP server running to connect to SPP.
☞ If the other module has any security enabled, additional steps may be necessary.

![Figure 3: Bluetooth Inquiry](image)

![Figure 4: Connecting to peer with SPP](image)

2.2 Bluetooth Low Energy (SPS)

Start searching for other Bluetooth Low Energy (LE) devices by running a discovery, as shown in Figure 5.

![Figure 5: Bluetooth LE discovery](image)

s-center collects all devices in the drop-down list. Selecting an entry from this list fills in the Bluetooth address, as shown in Figure 6. The u-blox proprietary Serial Port Service (SPS) [1] is the default and only protocol available for Bluetooth Low Energy (LE), so you only need to select Connect Peer.

The selected Bluetooth LE device can also be used in the GATT Client.

☞ To establish a Low Energy connection, the module used must be in the Central mode.
☞ The device that is connected to must have the SPS server running.

More information about SPS is provided in the u-connectXpress Low Energy Serial Port Service Protocol Specification [1].
2.3 Wi-Fi (TCP)

Connecting to another module over Wi-Fi involves several more steps, as you first need to connect to an access point and then to the module. The module can also be an access point, but it is important to separate the roles.

Start by performing a Wi-Fi scan as shown in Figure 7. The results are displayed in the drop-down list. Selecting an access point fills in its corresponding SSID, as shown in the form in Figure 8. The majority of values in this form can be left as default, but you may need to set the security mode and enter a passkey or password for that security mode before selecting Activate Wi-Fi. In this example, the security mode is WPA2 and the password is UBX-WIFI.

Once the connection is established with an access point, you can attempt to connect to a peer over TCP, as shown in Figure 9. The default protocol is TCP; enter only the IP address or host name and a port, then select Connect Peer.

The other module must have a TCP server running to connect over TCP.
3 Sending and receiving data

Once connected to a peer you can send data to the peer. Select **Data Mode** to send data, as shown in Figure 10.

In Data mode, the module sends raw bytes to the peer and no longer accepts AT commands. Any command is interpreted as raw bytes to send to the peer. Select **AT Mode** to return the module to command mode, as shown in Figure 10.

![Figure 10: Mode buttons, Data mode highlighted](image)

In Data mode, you select **Data Pump** to test the throughput performance of the module, as shown in Figure 11.

![Figure 11: Data Pump highlighted](image)

The default values are good, so you need only select **Start**, as shown in Figure 12. The data pump sends and expects to receive a sequence of bytes [0, 1, 2, …] (0 resets the sequence) and reports any deviations on the received data as byte errors. Only if the peer device is pumping data in this manner, can you rely on the byte errors (or lack of) to represent the link quality.

![Figure 12: Data Pump](image)
4 Settings for connecting to other modules

4.1 Bluetooth

To establish Bluetooth connections, the module must be discoverable, connectable, and pairable. Though it is not mandatory, setting a local name can help to easily find your device. To establish a low energy connection, low energy must be active. To initiate a low energy connection, the module must be in the Central mode while to allow incoming connections, the module must be in the Peripheral mode.

![Bluetooth connection settings](image)

Figure 13: Bluetooth connection settings

4.2 Wi-Fi

4.2.1 Station

Figure 14 shows the settings for Wi-Fi station. It contains more settings than those shown in the Basic Connection tab. Most notable is the ability to store and load the settings when you need to reset (restart) the module.

![Wi-Fi station settings](image)

Figure 14: Wi-Fi station settings
4.2.2 Access point

Figure 15 shows the Wi-Fi access point settings, including:

- SSID (the name "seen" by other modules)
- Security mode
- DHCP (if this module is to act as a DHCP server so that other connecting modules can be granted an IP address)

You can also store and load the settings in case you need to reset the module.

4.3 Enable servers

Figure 16 shows the server configuration. Here, you can view the currently running servers and set new ones. You must remove a server to set a new one in its place. In the example shown in Figure 16, the module is running an SPP server (id 0) and a TCP server.
5 Updating software

Selecting **Software Update** (shown in Figure 17) opens the software update dialog (shown in Figure 18). **Select File** allows you to browse for a new software file, and the **Software Update** dialog remembers the last 5 files used. The appropriate method is selected automatically once you select a file. In most cases, you must select **Software Update**.

⚠ A software update undoes all configurations on the device; consider saving them in **Configuring settings**.

![Software Update button](image)

**Figure 17: Software Update button**

![Software Update dialog](image)

**Figure 18: Software Update dialog**
6 Configuring settings

6.1 Saving and downloading all settings

To save the device configuration for later use, select Save Configuration from the File menu, as shown in Figure 19. You specify the location for saving the configuration in the prompt dialog.

The configuration is saved as a list of AT commands that can be used to recreate the current configuration. Selecting Download Configuration opens a dialog box from which you can select the specified file. The s-center software then runs all the AT commands to recreate the configuration. As it is run as a script, you can use this function to script procedures.

![Figure 19: File Menu](image)

6.2 Other settings

The rest of the tabs under Bluetooth and Wi-Fi contain various settings for different functionalities. The Advanced Connections and Settings tabs contain more general-purpose settings and some specialized settings. The settings are labeled with their respective AT command and all commands sent to the device are visible in a console window. For more detailed information about these commands, see the u-connectXpress short range AT commands manual [2]. Each tab can get and set their own subset of settings; select Get All and Set All to get and set all device settings, as shown in Figure 20.

☞ s-center populates some fields with default values until read. Select Set All to set the values in the module but note that these are not stored. Reset the module to undo any changes.

![Figure 20: Get and set all settings](image)
6.3 Retain or restore settings

Settings are first stored in volatile memory and are undone during module reset (restart). You must select **Store** to retain the settings in permanent memory, as shown in Figure 21. The module must be reset before the settings take effect.

Selecting **Store** conveniently resets the module after writing. You select **Factory** to undo the stored settings and restore factory defaults.

☞ Some settings are permanently stored through a separate command; these tabs have a separate option to store.

![Figure 21: Store and factory settings](image-url)
7 Miscellaneous features

7.1 Serial Settings

Figure 22 shows the Serial Settings tab. From here you can change settings of the serial port (baud rate, flow control, parity) as well as change which characters to use as command characters.

![Serial Settings](image)

**Figure 22: Serial Settings**

7.2 Data Mode settings

From the Data Mode tab shown in Figure 23 you can set the module start up mode and configure how the module handles and interprets the DSR and DTR pins.

![Data Mode settings](image)

**Figure 23: Data Mode settings**
7.3 GATT Server

Figure 24 shows the GATT Server settings. Form here you define the services and characteristics that clients interact with, read values clients have written to characteristics, and notify or indicate new values to the client. Characteristics are added to the latest service defined.

7.4 GATT Client

Figure 25 shows the GATT Client settings. From here you can establish an ACL link to a server by entering a Bluetooth address and selecting Connect GATT. Once connected to a server, you can Discover Services of that server and the services associated characteristics. You can then write the characteristics to the server or register to receive notifications.
7.5 Console Window

The console window shown in Figure 26 allows you to enter raw AT commands to the module and view the response. The console window also echoes the responses of AT commands sent as a result of interacting with the features of s-center. The console does not echo the sent commands, but the default behavior of the device is to send the command as part of the response.

![Console Window](image)

**Figure 26: Console Window**

7.6 User Defines

Figure 27 shows the User Defines tab. From here you can define and execute rudimentary macros. These macros consist of a list of AT commands delimited by `<LF>` in upper case. When executing a user define, s-center simply executes the AT commands in order with no special handling.

![User Defines](image)

**Figure 27: User defines**
7.7 GPIO

Allows you to configure the GPIO pins of the modules. As shown in Figure 28, select a pin first, then specify whether it is to be configured as Output, Input or Disabled, and finally how to configure it. Output pins can be configured with an initial value, low or high. Input pins can be configured regardless of whether pull resistors are used. Output pins can have a new value written to them and both input and output pins can be read.

Different GPIO pins are available for each module, as mentioned in the corresponding module documentation.

![GPIO configuration](image)

Figure 28: GPIO configuration

7.8 Wi-Fi Certificate

The Wi-Fi certificate tab allows you to upload and view certificates and keys for use with Wi-Fi station, as shown in Figure 29.

Only the name and MD5 of certificates and keys may be read, and not the contents.

![Wi-Fi certificate tab](image)

Figure 29: Wi-Fi certificate tab
## 7.9 NFC

The **NFC** tab allows you to enable or disable NFC. When NFC is read, the module sends a response.

![NFC settings](image)

### Figure 30: NFC

### 7.10 Bluetooth PAN

The **Bluetooth PAN** tab allows you to configure and establish or join an existing personal area network over Bluetooth.

![Bluetooth PAN settings](image)

### Figure 31: PAN settings

### 7.11 Ethernet

The **Ethernet** tab allows you to configure and establish an Ethernet connection.
7.12 Bridge

The Bridge tab allows you to bridge two or more interfaces.

7.13 Additional Wi-Fi Settings

The Network tab allows you to set various network interfaces with more control. For example, setting Wi-Fi station to use a specific IP address (static IP).
7.14 Bind Streams

The **Bind Streams** option (as shown in Figure 35) allows you to bind the streams of two peers to each other, such that the transmissions from peer 1 is received by peer 2 and vice versa. **Bind Channel** allows a third peer to be hooked up to an existing bind. **Bind Channel** also binds the peer displayed in the left drop-down list to the channel in the drop-down list prior to the Bind Channels button.

For more information about streams and channels refer to the u-connectXpress user guide [4].
7.15 MQTT

Figure 36 shows the MQTT form that allows you to establish contact to an MQTT broker. The placeholder text tells you what each field does. If any field is left blank, it is simply not included in the connection request.

Figure 36: MQTT form

7.16 EDM

In addition to Command (AT) Mode and Data Mode, the modules can also be placed in Extended Data Mode (EDM) which acts as sort of simultaneous AT and Data mode. In EDM mode, the commands and data must be packed in special packets and tagged with type.

Figure 37 shows the button to enter EDM, or if the module is already in EDM sets s-center accordingly. In EDM, s-center attempts to seamlessly handle the packages so the user can use s-center as normal. In EDM, you can send data to specific channels (peers) and s-center allows you to select this when it is applicable.

Figure 37: EDM button

7.17 HTTP

The HTTP tab can be seen in Figure 38. In the very basic use case of fetching for example a webpage it is enough to enter the address and select Go. A few options are available, such as changing the fetch method to ignore HTTP message 300 (redirects) and attaching content with the request – either as plain text or from a local file.

Figure 38: HTTP tab
**Figure 39** shows a request in flight. The request is indicated by the message at the bottom of the tab window, as shown in **Figure 39**. Any error is also reported here. After receiving a successful response, it is displayed in a new window, as shown in **Figure 40**. Here you can view the response headers and, if the response body is text based and sufficiently small, a preview. The response body is held entirely in memory, but only if the window remains open and can be saved permanently to file.

![Figure 39: Request sent, waiting for response](image)

![Figure 40: Response received and shown in a new window](image)
